2. Effect of substituting ferrites with ordinary resistors in PA circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-01 12:12:56 UTC
From: "Odd Erling N. Eriksen" <odderi@pvv.org>
Message-ID: <c9hrs8$3pm$1@orkan.itea.ntnu.no>
Source record: 25734

Hi,

I am currently trying to debug somebody else's UHF telemetry transmitter design. My primary concern at present is that the PA module (RF Micro-devices 2117) datasheet states that ferrites of certain values should be put in series with the bias voltage, power down control voltage and RF input.

On the PCB I am evaluating, the ferrites have been substituted with ordinary thick film SMD resistors of the same ohmic values.

My question, then, is the following: In what way is it likely that this affects the operation of the PA?

-Nonlinear operation because of noisy supply voltage?
-Excessive intermodulation due to stray RF being let into the chip?
-Anything else?

I am not very experienced in applied electronics, I am afraid - the MSc. studies I am currently undertaking focus (way to much!) on the theoretical approach. Sigh.

Thanks in advance for any qualified guesses!

> affects the operation of the PA?

-First you post, then you start thinking...

I assume the ferrites are ordinary ferrite beads - not some special kind of resistor. The ohmic value written in the datasheet then, is the impedance at the operating frequency, whereas the DC resistance of same will be near zero ohms.

Thus, the ferrites are not as much for preventing noise from entering the PA chip, as they are to prevent noise from _leaving_ the PA.

Am I right?

The MSc degree doesn't train you how to _be_ an engineer, it trains you how to _learn how to be_ an engineer. Since technology is constantly changing you have to retrain yourself constantly, so this is a good thing. If they just taught you what you needed _right now_ you'd be washed out and working in sales in less than five years.

Your follow-on is correct in that the ferrites are rated for their operating frequency, and should have low DC resistance (if they're surface mount they're not actually just beads, they're wires wrapped in ferrite. The term is a holdover from through-hole where they _were_ actually beads slipped over component leads). So replacing them with resistors means that the amplifier power lines are soft instead of stiff, which could do all sorts of weird things.

> writes:

To Len:
> >> Not quite it. In order to derive a control voltage for the
controlled
> >> oscillator, the PFD output MUST BE A FINITE WIDTH....

> >> ...BUT THERE IS ALWAYS A PHASE OFFSET.

Len,

This is actually _not_ the case as Joe (W3JDR), says.

Summary: The charge pump drives CURRENT into the main loop filter
capacitor forming another pole (at the origin, if I recall my control theory
correctly) or _integrator_.

Detail =
= = = = =

The charge pump is set up as follows. The PFD has two outputs, an UP
and DOWN. The UP output produces an output which is "active" or high (lets
make everything positive-true logic for this discussion) for a time period
which is the time from the edge of the reference to the edge of the VCO. So
that when the VCO drifts down, its edge is later and we get pulses. In
other words, we get pulses out equal to the time difference of the edges.
The DOWN is the converse.

Each output drives one half of the charge pump and as long as that
output is in its "active" state, the charge pump is providing _current_ into
the main loop filter capacitor. (lets assume that UP "pulses" means the VCO
it too low and VCO freq is proportinal to control voltage) When you get off
freq. the respective PFD output hits the rail and is in a _constant_ UP
state. Therefore, that half of the charge pump drives current into the
capacitor causing it to charge up at a rate equal to I/C. This is a simple
re-write of the capacitor formula I = C * dv/dt. This effect is another
integrator in the loop which gets you to zero phase error. As long as there
is a phase error, there will be a _CHANGE_ in control (or steering) line
voltage until you get to zero phase error and a stable control line.

If I again recall my control theory, this makes it a type 2 loop.

This does TWO things.

1) It drives the PFD pulses to zero making them as small as the logic
will allow thus

leaving the least amount of reference frequency energy to be removed
and

2) The integrator attenuates the higher freq harmonics of the reference
pulses that remain.

To be honest at this point, the loop filter will be a lag filter
which has

a finite high freq atten, but some loss none the less. Other
filtering is usually

required to further reduce the reference spurs. In communications
PLLs the fight

is between the filtering required to get the reference spurs down to
the desired

level and the classical lock time determining "loop filter". This
is because the phase of the reference spur

low pass filter starts to eat into the loop's phase margin and cause
more

ringing (poorer damping factor) as you require more reference
attenuation.

= =
= =

......

>
> OK, so where is the VCO control voltage coming from and how does
> it "know" how to reach the right voltage for the right frequency?

From the loop filter capacitor which stays charged when the PFD shuts up
at zero phase error.

...
> ...There will ALWAYS be a small error in any control loop...
> otherwise a control loop couldn't function to do controlling (basic
> control loop theory which so many seem to forget).

You are thinking of a type one loop and that's ok... Add the integrator
and (by theory & practice) you get zero phase error. I majored in control
theory & designed 2-way mobile PLL synthesizers. I also believe I designed
and built the first amateur, PLL synthesized 2M handheld (Motorola HT220) in
1973.

> A "charge pump" is basically a voltage-to-current converter to...

Actually, Len, the charge pumps I designed were a phase-to-*current*
converter. (Actually an edge-time-difference - to - current converter.

That is, when combined with the PFD. By itself, it was a pulse to current pulse converter. It was a current source which was turned on during the pulse. (two--one for UP & one for DOWN). Perhaps it should be called a "gated current source". During the UP or DOWN pulse, the respective current source is turned on at its full current.

> ... zero propagation delay to make such a...

If I recall the Fairchild improved 4044 used MATCHED delays in the two paths to minimize the dead zone as well as the opposite effect, overlap.

> ...The '44 is more complex...
> If there are more than two signal edges for every reference edge,
> the outputs hold at one state indicating a "way-off" ...

Yea, off frequency. So you DO know how it works by this statement. The phrase "hold at one state" _IS_ the key here in the charge-pump circuit. It will "hold the charge pump transistor on", continue to supply current (charge at a constant rate) to the cap causing the voltage to keep rising and the frequency to keep changing. When the phase error is zero, then the control line stops changing and the VCO is on freq.

> An op-amp integrator circuit functions as a sort of time-to-current-
> to-output-voltage converter ...

Ahhh! The "charge pump" does the same thing as a regular integrator increasing the loop type.

> Based on hands-on observation the PFD outputs
> ARE pulses at the reference frequency Their width
> is proportional to the integrated-averaged DC control voltage of the
> VCO when in lock.

You may have lost me here, Len. I think, in the type 1 loop you describe, the control voltage is the average-of-the-pulses (the phase error). I think you mean the "average of", not "integrated average of".

With the type 1 loop the VCO control line voltage would be the average of the phase error. So you would indeed require an error, but that's why we add the integration function in some loops.

Please note that by virtue of the VCO (having a voltage-to-frequency transfer characteristic) and the Phase detector (having a phase to voltage characteristic), there is already one built-in integration in the loop. This is because phase is the integral of frequency...or is it the other way 'round. (i always have to stop and draw a figure to state this freq/phase integral relationship...les-see... a step freq change integrates to a ramp--phase is the integral of freq, yea, that's it)

As I said earlier, I have watched the loop bounce around the dead zone - bumping up against the ends of the (zero phase) dead zone and producing mini correction charges to correct the frequency. I would often force some small current (sometimes with a reverse biased germanium diode) to stop the rumble

by forcing a small phase error.

Each integration in the loop gets you another level of "in lock"
accuracy. (i forget the official term), but

First is a frequency locked loop where, as you say here, there must be a small Frequency error to obtain the VCO voltage. Such as using a VCO with a discriminator instead of a PD. (frequency type 0)

Second is frequency lock loop with fixed phase error. (frequency type 1
phase type 0)

Third is the one with zero phase error. (frequency type 2)...etc

Each increase in type (or addition of a loop integrator) gets to a true _zero error_ for a higher order of input change. Starting with (although trivial a frequency locked loop with finite frequency error), freq, then phase, then ramping phase, then second order phase change (squared) ...but i digress...

> ...the "way-off" (phase errors larger than 180 degrees) conditions of
> the PFD outputs REMAIN in their fully-on ...

This is what Len meant, I believe, by "constant pumping". Not your usual, water-well pump metaphor, Len.

You get near the subject of "Capture Range" and "Lock Range" next. The XOR type PD has a lock range , or "pull-in Range" determined, in part, by the loop filter. More correctly by the loop bandwidth. If some of the XOR output square wave can't get through the loop filter (by being a low enough frequency) and drive the VCO toward the desired frequency, then it can't lock from far off freq. So it has a finite capture or pull-in frequency range. The PFD has an infinite pull-in (within the rails) per the above operation.

> ...However, integrated-averaged to DC, the outputs of the PFD make
> an excellent phase meter

(again I dislike the term "integrated average" here, but think "average" is what is intended) Very true (Without the charge pump). Just averaging the pulse width (phase difference). It is a phase-to-voltage converter. Then voltage makes the VCO get to freq.

> ...Ain't no "pump" pulses whatsoever at those "way-off" conditions.

Very true if you mean "pulses" with an off-time in between. Just a steady always on "pump" current at full current. This translates to "maximum ramp speed" of the VCO control line.

Joe

> >The XOR's big advantage is that it is simple, and there is no discontinuity
> >around the phase lock point (as there is in the PFD), but it does not

lock
> >up readily in the face of frequency errors.

You should say; "in the face of _large_ frequency errors".... the
"Capture Range" problem I mentioned above.

Joe:

> > The PFD's advantage is that it
> >readily locks up, even in the face of large frequency errors and it also
> >produces an easily filtered output.

Yep. Sorta' the ideal. Almost zero reference pulse energy and pull-in
range limited by the PFD rails and VCO range only.

> When you get the chance, grab a 'scope and look into the
> waveforms of a PFD as well as the control voltage. You will
> find out I'm right. No "theory" on that, just working PLL
> hardware.

As long as you have no charge pump or integrator, you are 100% correct.
Len. All the Motorola Pulsar car phones used the same charge pump for 0
phase error. This is still used now, but fractional N methods allow small
steps in freq (~5 kc) with high reference frequencies (~2 Mc) at the expense
of more logic.

If I confused who said what, I apologize.

Steve,

Good job. I concur 100%.

I quickly gave up on arguing this as it became clear to me that the number of words expended was increasing exponentially with the length of the thread. Arguing with some people is like surfing the web...you send a few bytes up and megabytes come back at you. I don't have the time or energy to play that game.

Right is right, and wrong is often long-winded.

Thanks for the support.

Joe

Another FB rig from Farhan! Seeing the new rig perched atop
"Experimental Methods in RF Design" convinced me to buy the book.

My favorite line from Farhan's description of the rig:

"This transceiver was designed during a six hour flight from Europe
with paper, pencil and the basic calculator built into my cell phone.
It was soldered in three sittings over three days. Very little went
wrong during the construction."

11. LSB problems with IC706MKII

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-02 14:32:28 UTC
From: chafik.philo@eudoramail.com
Message-ID: <cacbc942.0406020632.196e8ca4@posting.google.com>

Hello
I still have the problem with my IC-706MKII in LSB mode:
On all bands,I hardly get half output power on LSB, while on the
contrary ,
I get all available output power on USB.
About the modulation: the lower frequencies of my
voice are cut off, which produces bad modulation.
On recieve:
On LSB,the signal level is not as strong as on USB,
and some frequency components of the audio are
cut off;
the same symptoms appear when recieving Brodcast stations
(AM) on LSB.
Fortunatly,I can fix this annoying problem by rotating the IF shift
knob counterclockwise(about +800 or 1000HZ), so the the recieved
signal's level geos better
along with the audio quality.
So 1- I am looking for a way to fix this problem while transmitting.
I dont know if the LSB's BFO is off frequency, or
that the FI4 filter (which select the wanted SSB) is not realy
centered on 9.011.5 MHZ.
IF the first assumption is true , is there any way to change the
BFO frequency while
transmitting on LSB?
Yes, there is a menu in setup configuration (Q4) where one can
shift
carrier frequency (BFO) by +- 200Hz. But this is not enough.
2-
The Service Manual states the following:

****
IF SHIFT CIRCUIT:
==========
" The IF shift circuit shifts the center frequency of IF signals to
electronically shift the center frequency.
The IF shift circuit shifts the 1st LO and BFO within ï¿½1.2 kHz
in SSB/CW/RTTY modes or ï¿½250 Hz in CW-N/RTTY-N
modes. As a result, the 2nd IF (also 1st IF) is shifted from
the center frequency of the 2nd IF filter (FI4, FI5 or
optional IF filters). This means 2nd IF signals do not pass
through the center of the 2nd IF filter. Therefore, the higher
or lower frequency components of the IF are cut out. Since
the BFO frequency is also shifted the same value as the 1st

IF, frequency is corrected at the detector.
In the IC-706MKII, the 1st LO frequency is shifted to change the 2nd IF because a fixed 2nd LO frequency (60 MHz) is used. The 1st IF filter (FI1) and crystal filter (FI3) have 15 kHz pass-band widths, and do not affect IF shift operation.
....

BALANCED MODULATOR:
==========
Microphone signals from the AF selector switch (IC23) are applied to the balanced modulator (IC17, pin 6). The BFO signal from the PLL unit is applied to IC17 (pin 8) as a carrier signal.
IC17 is a double balanced mixer IC and outputs a double side band (DSB) signal with ï¿½40 dB of carrier suppression. R191 and R193 adjust the balanced level of IC1041 for maximum carrier suppression. The resulting signal passes through a 9 MHz IF filter (FI4 in SSB/CW/RTTY modes) to suppress unwanted side-band signals.
....

3-3-3 2ND LO AND REFERENCE OSCILLATOR CIRCUITS:
==========
The reference oscillator (X1, Q14) generates a 30.0 MHz frequency used for the 1st LO and BFO circuits as a system clock and for the 2nd LO signal.
....

3-3-4 BFO CIRCUIT:
==========
The DDS IC (IC12) generates a 10-bit digital signal. The signal is converted into an analog wave signal at the D/A converter (R116ï¿½R135). The analog wave is passed through the high-pass filter and low-pass filter. The 9 MHz BFO signal is then applied to the MAIN board via the "BFO" signal line
....

BFO FREQUENCY:
==========
RX BFO/3rd LO
TX BFO/FM PLL ref.
frequency [MHz]
frequency [MHz]
==========
==========

USB 9.0130
9.0130
LSB 9.0100
9.0100

CW 9.0106
9.0106
(ï¿½CW pitch frequency)

I think the first is true - the LSB BFO is off-frequency. If the filter
was not really centered on 9011.5 then USB would have problems too.

I think you have a broken crystal. (I don't have a 706 so I can't tell
you *which* crystal) I don't think any alignment problem can cause it
to be that far off-frequency.

I prefer a Fluke anyway. This is why:
When measuring resistances in a cabinet with a running Variable
Frequency Drive I got nothing but house numbers with the feature
rich no-name-multimeter, that I was using by then. When using
a Fluke I got correct readings. The reason: The cheap MM was
sensitive to the RFI, which the VFD generated - the Fluke was
undisturbed by the massive RFI. That was the model 77 which
is old now. But you may find a used one as a bargain.
If you want to measure with strong RF-fields present then there
is a difference and you get what you pay for. TANSTAAFL.
If you go for bench meters also konsider used Keithleys and
BBC Metrawatt.

Kind regards, Eike

On the other hand, I almost reached the point of insanity with a brand-
new Fluke 65 IR thermometer awhile back, trying to measure my car's
exhaust header temperatures with it. Every time I held it at the
(extremely awkward) position and orientation needed to aim the laser at
any of the exhaust ports, it would shut itself off.

The only thing that stopped me from sending it back to Circuit
Specialists for a refund was the fact that it would *only* shut off when
used under the hood of the car. I could never reproduce the problem
anywhere else around the house.

The problem turned out to be EMI from the Electromotive HPV aftermarket
ignition system. (After turning the ignition off, the thermometer
stopped shutting down.) Caveat mensor.

Fluke's DMMs do cost much more than generic ones. They guarantee accuracy that the others can't touch. I've always been amused that Radio Shack and many other inexpensive DMMs don't publish accuracy specifications.

If you want something for relative measurements (peaking, etc) and hobby use, you have a wider field available. If you use it for a living and it *has* to work - well, my Fluke 87 has served *me* wonderfully well. But modern IC technology has certainly made a lot of capability available for little cost elsewhere!

> (Please don't hold any errors against me. Check it yourself!)

Since Fred put that caveat in there, this is obviously nothing against
Fred, but...

We started with 8 watts assumed to be radiated (to find the max
farfield value). Area of a sphere is 4*pi*r^2. (Volume is
(4/3)*pi*r^3.) Seems like we want to say 8 watts/(4*pi*r^2) =
.0027w/m^2, and that yields a radius of about 15.4 meters, which would
actually be a good approximation of far field for 2M wavelength.
Units analysis is always a valuable check; also useful is a quick
mental-arithmetic check: a 1 meter radius sphere has a surface area
of roughly 12 square meters, so 8 watts at 1 meter will be about 2/3
watts per square meter.

OTOH, one would hope that the defib would be considerably less
sensitive than that, else cell phones pose a significant problem.

Cheers,
Tom

Heh heh, another one of those "long days..." :-)

I'm not going into control loops per se or argue formalized "types"
here. The original thread question was from someone worried
that the "dead zone" would cause instability if built with standard
logic gates. From there on it evolved into the usual type of
non-argument wherein one individual states an "inarguable"
case about only one control loop type...and no other argument
is allowed. :-)

[I should know better after doing computer-modem communications
for two decades but any response that says "wrong on all counts"
is a sure invite to a flame-fest... :-)]

Once upon a time three decades or so ago, I sat (as the subject
whose project was under scrutiny) in a design review where the
chief engineer of the division sat in with senior staff. I was
assured that my version of a wideband limiting amplifier "would
not work." That, despite, at the moment, it was undergoing
active temp test with monitored signals applied, etc. Wanting to
keep my job, I kept silent and agreed with "wiser heads" (two of
whom were sensed as believing me but kept silent, perhaps for
the same reason). Memos were written afterwards making note
of the comments, etc., but the design continued on as devised
and became a viable part of a system. Project team got nice

congratulations afterwards, a few patent awards, etc., plus
photos of individual smiling hand-shaking with the chief. Was not
the time to rub it in that my "unworkable" design did, indeed,
work. :-)

Those who have tangible, working hardware are often put upon by
newsgroupies who say "it won't work that way!" Okay, no problem
for me. If they say it doesn't work, well, that's it. I'll just go off for
a while and let the regulars have at it...while my stuff is working as
stated. :-)

[if anyone thinks control loops are an "easy" thing describable in a
few words...well, I don't think they've been really involved with such
hardware...but that's only my opinion]

Gotta love these newsgroups! :-)

Some of the cheep meters are fine for most home use. It is when you drop
them or accidently have them set for current or ohms while measuring voltage
you will notice the differance. Then again you can buy about 10 RS meters
for what a good Fluke will cost. It sure is hard to quit working long
enough to run to RS to get another meter while on a job that depends on
having a meter.

Sorry. Wasn't trying to even get some smoldering embers, Len. My
purpose was simply to report that the charge pump concept changes the loop
operation from what you had been describing to what Joe had been describing.
I, indeed, did jump into this somewhere in the middle as, thinking back
now, I don't recall having read the OP... Typical, eh?

> I'm not going into control loops per se or argue formalized "types"
> here.

Yes, as I was typing my 'type stuff' , I was also thinking..."Gee, this
is a typical go-off-and get-into-areas/detail-not-required-by-the-original
(as I thought it was) subject.

>... "inarguable" case......and no other argument is allowed. :-)

Yea. I didn't care for the strong wording Joe used. Joe's description was
in line with my experience, just his delivery...well. Sorry Joe. I hope I
didn't say something to that effect...

> ... Was not
> the time to rub it in that my "unworkable" design did, indeed,

My standard saying in control theory was something to the effect that
you had to put your normal fundamental sense about what is going on in
electronic theory in your back pocket.
I've spent months fighting spurs (well one anyway--I'm not that
bad--besedes it was early in my career), with everything filtered
imaginable, just to cut some ground plating in desparation to solve the
problem...

Actually, RS does specify the accuracy of at least one multimeter in
the manual for that meter: the RS digital multimeter PN 22-812. I sure
wouldn't depend on a Radio Shack multimeter in a work environment, though.
The ruggedness just isn't there.

I have a 'Heath by Fluke' model SM-77 which
works very well for me. It's not a true RMS
meter, which might be a problem for some though.
The newer models also measure capacitance and
frequency, but if all you want is a DMM this
one is fine. Fluke still makes this model,
under their own model number. (It's the
familiar narrow, tall meter with the 8 position
knob to the left side and 4 digit display).

I did manage to blow the low current fuse in the
meter (guess what, it comes with a spare fuse,
inside!). The 9 volt battery lasts forever
(think I've changed it twice in 20 years,
and one time was because I left the meter on
for a week straight!).

Good grief. Have you even TRIED looking? Type 'qrp' into
google and see what you find. Plan on lots of time sorting
through the THOUSANDS of useful links.

You'll get a lot more out of your 'journey' if you take some time
to put a little effort into it.

> by not paying for a name.

Perhaps. However, one thing that I've learned, after being in the
electronics/RF field for 25+ years, is that it is not wise to cut
corners on your test gear. It should be looked on as an investment as
opposed to an expense.

Fluke multimeters are, IMO, well worth the higher price for the
warranty, support, and how long they last.

Case in point: I bought an original model 77 back in 1984. Here it
is, 20 years later, and the thing is still with me and still working
great. I've checked its calibration three times in the entire time I've
had it (most recently, about two years ago), and it has always been
right on. I've gone through perhaps four batteries in that time as well.

Find me the "cheap one from Maplin or RS" that will compare to
that kind of durability and reliability, and I will cheerfully STFU.

Now, as to recommendations: Pretty much anything in the 20, 70, or
80 series will do nicely. Choose what you want based on what feature set
you want. Top of the line is, as I recall, the 87 series.

Be prepared to spend between $150-$400, depending on which model
you settle on.

Happy hunting.

What I would do first is a filter calibration. It's possible this will
fix your problem if you are lucky.
#1 You will need to enter the adjustment set mode. To do so, turn off
the radio.
Stick a dummy 3.5 mm "same size as headphone jack" plug into the
remote jack in the rear of the radio. "center pin is connected to
ground". Then, push the two left buttons, "p.amp/att" and "tuner/call"
in at the same time. While these two buttons are pressed at the same
time, turn on the power switch. The radio should crank up in the "set"
mode. Then, push F3 "TX" to enter the transmit set mode. Push up/down,
or maybe also the tuning or memory knob, to scroll through the
settings until you get to filter calibration. The display should show,
"GO FILTER CAL" when you get to the right one.
Have the radio connected to a dummy load, or matched antenna.
Push and hold menu "GO" to start the calibration. The radio will
transmit for a few seconds while it is calibrating the filters. It's
all automatic. This *should* cure your lopsided filter/carrier
oscillator problem. BTW, I don't know if it has any effect, but I
would re-center the IF shift to neutral before doing this adjustment.
When done, push F1 to exit the setup menu. It may turn the radio off,
but I forgot...If not, turn the radio off, take out the dummy plug,
and turn the radio back on normally. If you are lucky, it will be

fixed. I've done this on mine when I noticed the filters were getting a little lopsided. When the filter setup is correct, you should be able to listen to "white" band noise, switching between USB, or LSB, and notice no real change in pitch. "IF shift nuetral".
These radios do automatically what we used to have to do manually as part of the alignment. Do a search, and d/l the complete 706mk2g service manual for complete instructions on this, and all the other setup's...I wouldn't mess with any other than the filter setup. If it ain't broke in other areas, don't fix it...:/ MK

Greg,

In my opinion, the best QRP Group is QRP-ARCI. You can check them out at
http://www.qrparci.org

They publish a very nice quarterly magazine called the QRP Quarterly, and
unlike a lot of other club journals, it's usually published on time.

For a neat SWR meter, check out the NoGA QRP group from Northern Georgia.
http://www.nogaqrp.org/ They have a neat little SWR/PWR meter kit they
sell, or used to sell.

The QRP ARCI page has about 100 links to other QRP clubs all over the world.
You won't have a hard time finding info there.

Greg

The online group is QRP-L at qth.net. Be aware that this is a pretty busy reflector, however. Thereis also a QRP reflector at qth which is very low key.

Someone mentioned ARCI, which is a very good organization. There are two other big QRP groups. The American QRP club (www.amqrp.org) tends to be a little more focused on homebrewing than ARCI. AmQRP is more like an association of clubs. They were formed by the merger of NorCal and NJQRP, but work with a half-dozen regional clubs to produce kits and conferences. Their magazine, Homebrewer, is a little better than QQ in my opinion (maybe because I'm more into melting solder). The G-QRP club is another great organization. They publish a magazine called Sprat which has been around forever it seems. Personally, I'm not as big a fan of Sprat because they tend to use a lot of parts in their designs which are harder to get on this side of the pond, but on the other hand, if you are on the G-land side of the pond, those are probably easier to get. They have produced a number of kits, many of which are available from Kanga U.S. on this side of the pond. The DL-QRP club also has a number of kits. Theirs seem to be a little more "polished" than the G-QRP kits which are pretty different.

Besides these three biggies, there are perhaps a dozen other clubs that publish online and/or offer kits. The Flying Pigs QRP club is more about kits and contests than publications. Someone mentioned the North Georgia QRP club, which has that neat SWR/Power meter. The Arizona ScQRPions currently has a neat paddle kit. Seems like there are several others which escape me at the moment.

ARCI runs a big conference in conjunction with the Dayton hamfest every year which is a wonderful place to learn, get parts, and meet other QRPers. AmQRP supports a handful of conferences, including Atlanticon and Pacificon in the spring, Ozarkcon just passed, and Lobstercon coming up. The ScQRPions are running a conference near Flagstaff around the first of July. G-QRP runs conferences in England and Ireland, too, but they seem to be somewhat more erratic than the ones in the states. DL-QRP also runs an annual conference.

So yeah, plenty of resources, and an amazingly friendly bunch as well.

..

Thank you for all the suggestions. The qrp groups are what I have been looking for. To one of the previous posters, I find that part of research is asking questions and what better place than a group that has experience in homebrew. I had done my research prior: google, local vhf net, hf. I was wondering if there were more obscure groups that deal with qrp and some people helped me out. I hope other hams that are interested in getiing into the fundamentals of amateur radio are not "welcomed" in the same way. As qrp is on the upswing of popularity, more and more people interested in homebrewing will be asking questions.

Thanks again for the help. One day I may be able to return the favor.

If you're on a tight budget, these things are hard to beat --

http://www.harborfreight.com/cpi/ctaf/Category.taf?categoryid=170&pricetype=S

Yes, three bucks. They won't hold a candle to a Fluke, but for doing simple voltages or resistances, they're hard to beat. They're accurate (at least the ones I've tested) within 1 or 2%, at least for DC and AC voltage (I don't expect them to do accurate RMS readings on non sinusoidal signals, however) and resistances.

They're cheap enough that you can dedicate them to a given operation -- you need to know the voltage on your power battery all the time? No problem -- just slap one of these on it.

Personally, I own like ten of these things, scattered throughout the house and car, and a few better multi-meters for when I need them.

Over 200 projects, many with photo's and most with PCB patterns (BMP 250pixels/inch), even small PDF library and homebrew messageboard.

Latest project is DIY IF cans for valves (tubes) complete with on-line calculators for the coils. Inc. Photographs.

Would be interested to hear whether anyone has any suggestions for multi-gand tuning caps (100pf or more). I have been shoving tapered PCB strips between other and it works a treat, but there must be simpler methods. Also tried sponge/PCB sandwich with bolt compressor. Also works well, but capacity limited. Ideas anyone? (Not interested in varicaps/varactor diodes. They don't work so well with 250vDC!)

Do you want a variable or a preset? If a preset, have you thought of using
double sided PCB. One side un-etch, the other etched to give a series of
lands that reduce in area. Connect more lands to increase capacitance.

I saw the idea somewhere, so don't claim it as my own.

<< Tom-

You caught me!

I don't have a calculator handy, but it seems to me that the correct formula yields an even lower power when spread over three times the area.
>>

Caught again!

I took another look at my earlier calculations and found that not only did I have the wrong formula for the area of a sphere, I had my equation upside down! I ended up with something like watts per square meter equals square meters per watt. Yes, the power is spread over a greater area, but that did not compensate for the really stupid mistake.

So, if one volt per meter equals 2.7 milliWatts per square Meter, that field strength would be generated by a five watt handheld radio at a distance of 15.4 Meters, which is about 50 Feet. This is sounding serious unless the defibrillator has a greater tolerance. I certainly hope it does, since we are often irradiated by passing mobile radios running 50 watts or so, at closer distances than 50 feet.

Lets see - 50 watts is ten dB greater, so the distance would be about 3 times as great as 5 watts, or about 150 feet for one volt per meter. Or, maybe I should just keep my mouth shut to keep from screwing up again!

I echo what Eike has said. I own and use an older 85 (also gave one to a son to take to University). It works in all conditions including, something especially important one would think to this group, in the presence of a lot of RF.
The low resistance range has been invaluable. The sensitive AC range allowed me with ease to tell if 240 VAC water heating elements were operating by measuring the voltage across the straps going to the elements. (Not between!) Recently, I used the capacitance feature to verify that a control line was almost certainly open at its far end (that was a long way up a hot tower).
Good tools pay! I can raise penny pinching to an art form, but I use Klein safety harnesses, HP calculator, and Fluke meter. 73 Mac N8TT
P.S. My answer to the question is to buy something in the 80 series.

Visit http://www.fpqrp.com for more information on the Flying Pigs QRP Club International.

They used to publish a pretty decent monthly newsletter in PDF form, it's free.

This club is pretty laid back, they have an email reflector but be warned, it's likely to carry a lot of friendly conversation among the technical posts. However, you won't get flamed for asking a technical question...no matter how simple it may be.

They have no dues, no rules, no regular meetings...the Flying Pigs are more like a state of mind.

The Flying Pigs QRP Club International has sponsored, along with the Northern Georgia QRP Club (NoGA), the annual "Buildathon" event at FDIM during Dayton for the last three years in a row. Some very NICE homebrew devices have come from those Buildathons....freq counters, SWR/PWR meters, Freq Standards...etc

If you want a fun place to hang out and a great group of hams to hang with, join the Flying Pigs QRP Club International. We even have a club beer mug!

Right! They even come with the 9v battery included and they have a
transistor
test function, to boot. When you spend 3 dollars on a DMM, you're not
looking
for precision results. And you don't need a precision meter for most
measurements.
As a secondary meter, these 3 dollar things cannot be beat. When I
needed to
do 6 simultaneous measurements (a DC-DC converter I made with dual
outputs -
I needed to measure voltage and current on the input, and voltage and
current on
both outputs) I bought 4 of them. They were more accurate than I
thought they
would be - and more accurate than I needed.

Tnx Ed, et al.

Duly noted are the "magic notch,' the Datong FL1/3, & the "monitor's pal"
hetrodyne hunter-killers.

Tnx

But, still haven't got an answer about the Rad-Shark's guts & possible
mod. But perhaps that's a futile quest.

Why do I ask at all? Well to replace the lost adjustable-peak audio
filter in a Navy RAL regen. That's why.

Again, tnx

Marty

>> of interest

A Cohn filter covering 1.75-7.2kHz, is shown on
http://home.online.no/~la8ak/c11.htm
some Cohn filters have been published and turned out to be extremely
difficult to copy, but LA7MI claims this is quite easy to make.
Perhaps somebody could scaLe the values down to the mediumwave band?

I've received some more requests for such construction, so I am not
worried whether this writer needed a simple filter or not, it is a lot
of demands for useful solutions

The SBE-33 and 34 circuits (plus a rig from QST "transceive with
transistors")
are bidirectional, but only in one direction at a time. The direction
of operation is switched with the ptt circuit. I think he means in
both directions at the same time, as would be used in full duplex
phone circuits.

Hi Jim

Yes, I also prefer the Fluke meters. I own a bench and handheld model.

They have a lifetime warranty and are a good investment new or used.

Many good models available on ebay from the big tech sellers at a good price.

judy

i have compeleted the bidirectional transceiver for which i was
seeking this info. it has been posted on this group and you can view
it on http://farhan.net.co.nr.
the bidirectional amplifiers do not use transformers, they are RC
coupled and they have proven to be quite stable.

<< I am considering purchasing a Fluke meter to do some
alignments & repairs here.
Can anyone reccomend a Fluke meter model or anothere brand model? >>

Clint-

I like the idea of having a couple of those cheap meters. I keep one in my brief case and one I take with me on trips.

For the shop, I wanted something I could depend on, so back in about 1980 I purchased a Fluke 8020A handheld digital multimeter. Soon after that the display darkened. I purchased an upgraded display, installed it myself, and have had no other problems since then.

Three years ago I bought a Fluke 8012A bench model digital multimeter at a Hamfest for $40. It looked rough and was missing its power cord and probes. With just probes and a new cord, it appears to be working perfectly. Comparing it with the old 8020A, readings of various voltages and precision resistors were identical, except for a 0.01 volt difference when reading a 13.8 volt power supply. I know that the 8020A has never been calibrated since leaving the factory.

About a year later I bought a Fluke 8050A bench model digital multimeter in non-working condition, for $35. This model has one more digit of resolution than the other two meters, and has true RMS on AC. The problem turned out to be that it had dead internal batteries, and required the batteries to act as a voltage regulator when operated on AC. Some slightly smaller batteries from Radio Shack made it work. Again, it appears to be working perfectly. Voltage and resistance readings agree with both other meters. (I forget which one of the three was 0.01 volt off on 13.8!)

The moral of the story is that here are three meters approaching 25 years of age, that have maintained their accuracy in spite of rough handling over the years.

I would recommend any of the three models if you can find a used one. Of course, you may find that someone has mis-calibrated it, so you need some assurance it is still accurate. Perhaps you can scrape together a handful of precision resistors and use them as a "standard".

If you want a more modern meter, the latest Flukes offer auto-ranging. The early versions sacrificed some accuracy and were slow, but I understand more recent models are better. However, I'm not willing to spend the money for auto-ranging when my old fixed-range meters are so good!

73, Fred, K4DII

strange... believe I bought the 8020B already in 1980, but after a
while I had to put some paper under the pcb to push the contact harder
against the display to obtain proper reading. Still have some 8020B's
but they usually don't work properly too often.

One strange fault occurred when I tried to measure the booster voltage
in a tv set, the varistor for input protection blow, and I had to look
for some resistor-looking type. The resistance measurement wouldn't go
higher than 100-150k until the varistor was replaced

hello

Help!!!

how do you include pcb cutouts (ie for mounting rf power transistor) on the design using easy pc programe..I have tried and am at the stage of burning the computer..so not much luck..

thanks simon

Well the RFG-30 quit on me again, so this time I had to get into the package
to find out what was the matter. Pete, KE9OA, said something about removing
an overlay, which at the time went by me without even pausing at my brain.
But faced now with this puzzle, I looked and looked, and eventually I could
see where sheetmetal screws came down through the aluminum top panel, but
there were no screw heads visible above them. They had to be covered up
with something, so I started tapping on the flat surface around the on/off
switch, and sure enough in places it sounded thin and hollow. So I got a
sharp little screwdriver and found a corner that looked like there was space
around a thin covering and started to pry up on the corner of that covering,
and what do you know - - it was a thin "overlay" (now I know what an overlay
is) that was glued down to the plastic top panel with rubber cement, and it
came up fairly easily, exposing the four Philips-head sheetmetal screws that
needed to be removed to get down to the aluminum top panel holding the
on/off switch.

So there you have it. Now the halves of the case can be separated and
re-arranged to service the innards of the machine. One thing surprised me,
though. I found a whole lot of stored energy in the 1000 uf 50 volt filter

capacitor, and it stayed charged up to around 40 volts between the times the unit was turned on. Now 40 volts is something to be a little concerned about. I remember being zapped by a 45 volt "B" battery when I was a kid, so this thing is not so different. If shorted, the sound of that arc is sure to attract some attention from people nearby. Okay, it's not deadly, but a little bleeder resistor across that 40 volt supply wouldn't hurt.

I found help servicing this unit from the 1986 Metcal patent 4,626,767 which contains a pretty accurate circuit diagram of the RF and power supply sections of the RFG-30, missing only the use of the SG3526. You can view and print out this patent by using http://www.pat2pdf.com/ which will turn the document into a PDF file you can download. I wasn't able to find out much from their other patents about the use of the SG3526 where they (oddly to me) ground the A and B outputs of the chip, but the OnSemi data sheet from http://www.newrock.com.cn/pdf/igbtgo/SG3526.pdf shows an application in figure 21 that looks like it's probably how they're using it. If anyone knows of a source of more recent schematics on the RFG-30, the PS2 or MX-500 power supplies, this is a good place to let all the people that are interested see them. I found a 1N4001 diode that passes rectified pulses to the 470 uf 25 v filter capacitor on the 16 volt supply, I think it was D7, bad, and replaced it, restoring operation.

Hi All,

I am looking for homebrew designs for the Barker & Williamson 90ft or 180ft 1.8-30MHz Broadband Folded Dipole. also intersted in desgins based on the isotron.

Thanks,

Warm up your search engine and put in TTFD and T2FD. The two best articles will be on the Harc-Core DX site and the Radio Havana mirror site. This antenna has also been covered in Monitoring Times and Popular Communications, twice in each. This is my favorite antenna and I've built several. If you are not going to transmit you can even build it cheaper. Holler if you want to know more.

http://www.hard-core-dx.com/nordicdx/antenna/wire/t2design.html

The consensus about these antennas seems to be that they're very
convenient, but can be quite inefficient if you're using them on
frequencies well away from those where the dipole is resonant.

> also intersted in desgins based on the
>isotron.

I don't have a good sense of how the Isotron is _supposed_ to work
(according to its manufacturer). What little I've heard of its actual
use in the field suggests to me that it, like many other "miracle"
short vertical antennas, is actually very dependent on radiation from
its coaxial feedline and its support mast. The Isotron itself seems
to act less as a radiator, and more as a sort of end-of-feedline
transmatch between the 50-ohm coax (interior) and the mast and coax
braid. Trying to reproduce one, homebrew, and to get good performance
thereby seems to me to be a recipe for severe frustration.

Hi Jan-Martin,

It may depend on the browser you use, but if you have Adobe Acrobat Reader installed and linked to your browser, clicking on the link John provided should open the ap note, and at least in Internet Explorer and Netscape Navigator, you can then save, not from the "file" menu but from the disk icon that shows at the top of the IE or NN window displaying the ap note. Or, what I did is just right-mouse-click the link instead of opening it, and tell it to save the file. Warning: it's over five megabytes.

Anyway, that link is the whole file...

If you go to the Linear Technology web site, I'll bet you can find it by doing a search for an47, or an47fa, or whatever. (Though I haven't tried that, since it's downloading just fine from the link John provided. Thanks--once again--John!)

Cheers,
Tom

Re the Isotron.

You may wish to look up an IEE paper on Electric Slot Radiators by
Robert K. Zimmerman Jr.

I thought the same as you before I tried one.

One test was to by-pass the feeder altogether. I connected a simple
crystal controlled 160m 1w rig directly to the feed point. Using an AEA
analyser brought the antenna to resonance.

I then measured the field strength using a Potomac FIM.

I then added 15 metres of 1/2" Cellflex as a feeder, relocated the
transmitter, made an insignificant adjustment to the antenna and took
another reading.

The loss through the short length of cable was only around a dB.

I was the very first person to get Ralph at the factory to design a AM
broadcast band version for the low power (1w EMRP) license holders here
in the UK.

A well setup station, at the top end of the band typically covers a 5
-10 mile radius with reception on a portable radio. The end users are
happy with that as the terms of the license only allow coverage over the
campus!

I'd use a CPLD - it'll be faster, cheaper and take up less board space. You
can use it for the rest of the logic as well, including the phase detector.

The 74HC390, a dual decade counter in one package, has a maximum
clock frequency of 66MHz, and is readily available (or at least a lot
more so than the AS or S package -- less power draw too).

This page has complete info about the terminated folded wideband
dipole:

http://www.cebik.com/wbfd.html

This page has the index for many interesting antennae:

http://www.cebik.com/radio.html

This gentleman's site is about the best (in my opinion)
for all sorts of antenna information.

CPLDs are one option, though I don't know enough about them as yet
to say for certain how easy or difficult it would be to design one in.

Here are a couple of links that may help.

http://www.xilinx.com/xlnx/xil_prodcat_product.jsp?title=cpldsolutions_cpldlearn_page

http://www.xilinx.com/xlnx/xil_prodcat_product.jsp?title=design_kit

The designer's kit will run you about $50.

Happy hunting.

But given that the '192 is programmable, and this is a synthesizer
application, I suspect he wants the '192 for the divide by N counter
chain, not a fixed divider.

Have you considered the 74AC series? The 74ac74 will go well above 100 MHz.
Prescale by 4 with these and then use slower presettable counters.

Or the 74HC/HCT4059 is guaranteed to do over 20 MHz and typically 50 MHz and
is a 16-bit presetable counter. Probably very hard to find these days.

You can check out Xilinx's free design SW (includes CPLD stuff)
starting here:

http://www.xilinx.com/xlnx/xebiz/designResources/ip_product_details.jsp?key=DS-ISE-WEBPACK

I guess Altera and Atmel also have free or low-cost design solutions.
See, for example, the Atmel ATF15xx-DK2 sold by DigiKey and others.
But the problem is that you still have to actually program the parts,
and that can be a barrier. It's just something you have to commit to
doing, and perhaps spending either some time or some money to put the
right environment in place to make the programming easy. For example,
you can buy a JTAG programmer from Xilinx that plugs into the parallel
port of a PC, and perhaps they still provide an ap note with the
schematic if you wanted to make your own. However, once you do get
over the barrier, the rewards can be great: you can pack quite a lot
into a single CPLD, and you can change it just by re-programming when
you discover a mistake or an improvement. The re-programming can be
(is generally best done) in-circuit, so there's no unsoldering
involved. A single tiny CPLD can have hundreds of flip-flops, with
associated logic.

On the other hand, have you investigated other solutions? I didn't
see your original posting, but suppose that there must be 74AC/74ACT
parts that will clock plenty fast enough, and there are some nice PLL
chips from folks like Analog Devices and National Semiconductor with
built-in programmable dividers for both reference and oscillator
inputs, and they can go up into the GHz region for the oscillator
inputs. (They may appear at first to have TOO HIGH a minimum
frequency, but if you get a dual one designed for both RF and IF
range, you'll probably find that the IF range section will go low
enough.) They are compact and inexpensive.

Cheers,
Tom

Wow! I did not anticipare such a wonder ful response. Thank you very much all.

I will take *all* of your advice actually - I will use the 74AC192 for the divide-by-N counters and try my hand at PLD's for the PLL and peripheral circuitry.

I run Linux and can program Perl blindfolded, so writing a programmer will be no problem :-)

Again, many, many thanks!

The last issue of QST had a short article on the CircuitMaker Student edition circuit design package. I downloaded it and spent several hours trying various oscillator designs (including the phase shift oscillator discussed in the same issue of QST). I couldn't get any of the designs to oscillate! I was mainly trying Colpitts oscillators.

Has anyone else tried designing oscillatos with this application?

Thanks,
Ed Bailen

Ed, I don't have any experience of CircuitMaker but I do have trouble with
getting oscillators to oscillate on other simulation packages. This is
inherent in the design of the simulators in that they will deliberately try
to stabilise the circuit and stop the oscillation from taking off!

If you have an option in there to 'skip initial transient solution' or
something similar, it's good to check the box and bypass it - this is the
thing that tries to DC stabilise the circuit. From there, it relies on
noise to get the oscillator start and if there isn't any, it won't...

<< What I would do first is a filter calibration. It's possible this will fix your problem if you are lucky. >>

Mark-

I have the older IC-706, and your instructions worked perfectly on it as well. However, I couldn't tell any difference in the sound between USB and LSB after the calibration was complete.

The difference in sound isn't extreme, just enough to be annoying. Further, it is about the same with both the normal filter and the narrow SSB filter. I tried the calibration with both filters, although the "NAR" indication goes off while the process is being completed. I also tried it with the IF shift at both extremes, with no noticeable difference in the results.

Any other ideas?

They are good.

For what it is worth, I bought a big Fluke 5 1/2 digit 8520A ten or more years back used. It is still going strong. I hardly ever use some of its fancy features, but I do use 4-wire resistance sometimes. It is hardly portable (rack mount size) but great on the bench.

Here's a story about its resistance to abuse:

At some flea market I once acquired some strange glass encapsulated resistors. They were at least an inch long and very high resistance (100Mohm or more as I recall). It occured to me I could use one or two to make a nice HV probe. So I built a divider inside a plastic tube. I found a HV dc/dc supply in my junk that I think was in the 1-2 kv range. I turned it on, and tried measuring with my new probe plugged into my Fluke. The plastic tube was clear, and to by horror, when I touched the probe on the HV the glass resistor lit up. (I'm guessing they were gas filled to do this on purpose, but I really have no clue why it happened -- the voltage should not have jumped the gap in air.)

So as I see this happening in the probe, I hear the Fluke make strange unpleasant clicking noises. I look over at my favorite meter and the display is now in Klingon. With great sadness I power cycle the meter and to my amazement the meter looks fine. I have never seen any indication that anything was permanently injured. Try that with a cheapo meter.

Not that I have anything against the cheap ones -- I have several.

Typically, an oscillator is just a noise amplifier with some frequency selective feedback. In a real oscillator, there is always some wide band thermal noise present, which is amplified, some selected frequencies are circulated back to the input and reamplified and so on. Finally, there is going to be a narrow spectral line and a wide band noise floor due to the thermal noise, assuming of course that the phase, amplification and feedback loss conditions are correct.

If the simulator does not simulate the thermal noise inherent in all resistors and semiconductors in temperatures above absolute zero, it is not very likely that the design would oscillate. Inject a very low level wide band noise into the amplifying stage and the oscillation should start. However, I have never seen the CircuitMaker or how to generate a wide band noise signal with it.

Injecting a pulse usually works with SPICE, I've found.

105. Jameco and substituted parts

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-07 12:02:45 UTC
From: Paul_Morphy <nopaul_morphy2@coolgoose.com>
Message-ID: <FPYwc.19536$Gx4.1124@bgtnsc04-news.ops.worldnet.att.net>
Source record: 25687

I've had good service from Jameco over the years but -- I recently ordered 2N5484 FETs from them. The datasheet they have on their site is the same as Fairchild's, so I figured I would be getting a prime part. If you've used 2N5484s, you know why I wanted that particular part. What they sent, however, was NTE312s. The Idss spec for the NTE312 is 5-15 mA, vs 1-5 mA for the 2N5484. I tested a few of the NTE312s and confirmed the bad news. So beware of Jameco when ordering active parts. You may not get what their Website and catalog say. In the case of the FETs, in a reasonable quantity, Mouser has the Fairchild 2N5484s for the same price.

I had the same experience with MAX232's -- they were listed as Maxim parts
and a non-Maxim was sent (it works fine, however.)

Yes, has happened to me too !

If the part can't be substituted, I telephone the order
and specify do not substitute and that works about
9 out of ten times with jameco and mouser.

Some times too, the information placed into their computer isn't correct. I ordered some parts for a radio repair once - from a company. They sent me what was "supposed" to be the correct part (SUB), in this case a Transistor.... What I needed was an NPN. I didn't bother to check it, as I was busy and I figured they knew what they were doing. I placed the part in the radio and since it was the only part in that unit I had to replace, I fired it up. Snap, crackle, pop. I ain't talking Rice Krispies. I seen smoke. I knew all the other parts were ok, so I took the transistor back out and looked at it. I looked the number up - personally, which turned out to be a "PNP". WOW. So much for trusting. I called the company, spoke to the tech of that firm. He at first swore it was the cross for what I ordered - while looking at the computer records they had. I said NO, the part I ordered and this was crossed for, is an NPN. This is a PNP. He checked in their cross reference book and then the computer again. He found the computer had the wrong cross type listed. He apologized and corrected it right there and then, then asked me again the part number I needed. I told him. He took care of that, which he said would be free of charge. He then asked if any other parts were damaged - they would send free of cost or if I wanted them to reimburse me labor for my time. I said no to both. It was no big deal, but the right part would be nice. I got it in short order, placed it in and whalah, the set was working. So, that company was very apologetic about the error and willing to make amends. While that may be a somewhat different scenario from "substitutes" as listed below, I guess the caveat here is make sure you check the parts BEFORE you place them in service. It could save some headaches. I learned about the same time to never trust "new" parts. To always check them if possible before placing in the circuit - as I've bought "new" components in stores such as Radio Shack, only to bring them home and find them defective. Those events were in my early years of getting into Electronics. Lessons I've carried through to this day. IF you have enough data available, or maybe to ask in here, you're better off to try to shoot for a couple subs, just in case the company you deal with doesn't have one and maybe not the other - especially listed AS subs. I try to leave nothing to chance anymore. You can't always trust the phone sales help. They go by what is in their computers. Most of them are clueless when it comes to electronics. Some people tend to forget this. IF you find a company that stocks many items of interest, such as Mouser or whoever, you're better off dealing with them to save all the hassle of sending here and there for parts and end up losing time and paying more in shipping than what the damned part or project may be worth. I have 3 companies I deal with basically. The rest I use sparingly. Mouser is one of those I use. For the record, I don't recall the company I got the "wrong" part from as aforementioned. But as I said, they did remedy it.

The last time I ordered from Jameco was years ago, back in the Z80 cpu days,
I ordered a Z80B (6mhz cpu) and they sent me a Z80C (4mhz). Never ordered
from them again. Buyer beware.
thanks, John.

112. EXCELLENT price for 1-4 Layers prototype PCB

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-07 20:02:49 UTC
From: tigeryesh@hotmail.com
Message-ID: <e04d9f77.0406071202.114fee5f@posting.google.com>
Source record: 25694

NOW Gold Phoenix offers an EXCELLENT price for 1-4 Layers prototype
PCB.
(Our website http://ca.goldphoenixpcb.com or http://24.226.35.46)

ONLY US65 include shipping (Lead time 5 days, FedEx or UPS need 2-3
business days from China to North America)

1.MULTI-Designs ON A SIGNAL PANEL IS NOT ALLOWED
2.NO LIMIT ON THE NUMBER OF VIAS
3.MAXIMUM ONE INNER CUT PER BOARD
4.FREE SETP AND REPEAT SERVICE IS PROVIDE, SCORE LINES IS ALLOWED
5.1-2 Layers ,FR4 material,0.062",1oz Copper.
6.Minimum hole size 20mil, minimum clearance 8mil.
7.Green solder mask, white silkscreen
8.Total area of all boards combined less than 155inch sq. Maximum
size per board 10X14.5inch.
9.ONLY Gerber274X and NC Drill files are accepted

For example, If the area of your boards is 10 inch sq, US65 Gold
Phoenix will make 15pcs for you!
If you just want 1pcs the maximum size of your board is 10"x14.5"

10. 4 Layers PCB,Free shipping,Free Testing:

US200 155inch sq
US185 100inch sq
US165 75 inch sq

For example, If the area of your boards is 10 inch sq, US200 Gold
Phoenix will make 15pcs 4 Layers
board for you! If you just want 1pcs the maximum size of your board is
10"x14.5

Jameco is a pretty good company. I've never had any problems with them.
I don't suppose you bothered to let them know they sent you the wrong
part. Anyone can make a mistake.

I do not believe this is necessary. The normal charge-up of any coupling caps will get you "off center" at the start. On PSpice ver 9 one of my students "couldn't get an oscillator to go". I lenghtend the simulation time and found that it took longer than he had set for the transient analysis.
Out of the box on PSpice I got both a 555 and Colpitts to fly. I can't speak to CircuitMaker, but there may be analysis set-up parameters such as the aforementioned initial condition which may be the key. PSpice also has something about "skipping" an initial transient state/solution which I haven't experimented with to comment further, but could be a consideration. Watch the options...

I have found that that generating a narrow pulse with a current source works well for me. The oscillator gets going rather quickly because the narrow pulse has a wide frequency spectrum and since the ideal current source is an open it doesn't impact the circuit operation.

<snip badly-spelled ad>

Now why would I want to go with a completely unknown and unproven
(to me, at least) firm, one that can't even spell parts of their
advertisement right, when I can pay just a bit more and get local
service from a US-based company that I know won't have any trouble
turning the boards I need around?

BTW... *PLONK!*

I remember loading a ham friend's Viking Ranger (60 to 80W) into a 75
ohm dipole without a balun, and then squeezing the pickle and being
introduced to a rather nasty fellow called R.F. Burns. :-(It's not
nice to have a coax that radiates!

> Out of the box on PSpice I got both a 555 and Colpitts to fly.

The 555 should start unconditionally, since it is based of the RC time constant and two comparator levels. Thus, it should not matter, what the initial charge in C is, since sooner or later one of the comparators will change state.

A startup transient in the Colpitts may very well start the oscillation, since the transient is rich of harmonics and if one of the harmonics is connected back with sufficient gain through the frequency selective feedback, the oscillation should start.

There was some sort of dual tetrode (6164?) that used to be used in high
performance mixers for valve radios.

Source record: 25607

I'd like to learn a bit more about this, since all the analyses I've seen have assumed a uniform flux density in the core material. And I've always assumed that this is a good assumption for high permeability materials at least.

According to conventional analysis, for a given permeability, current, and number of turns, the flux density is inversely proportional to the magnetic path length. For a toroidal core, this path length is taken to be pi times the average of core ID and OD, so the net result is that the flux density will be higher in a bead than a larger core, all else being equal. But it's due to the shorter bead magnetic path length rather than the distance of the core from the wire going through the middle. Other core shapes, such as EI and pot cores, also obey the path length rule.

Other parameters, such as the amount of inductance or impedance per turn squared, also depend on the path length, as well as the core permeability and the cross sectional area of the magnetic path. So if you hold one of these other parameters constant as you vary the core size or shape, you can reach different conclusions about the effect of the variations.

I'm not going to check you gentlemen's math -- it sounds like you've gone through that pretty thoroughly. But I'll point out that you're calculating the field strength from an isotropic source in free space. Let me remind the readers that this is the absolute lowest possible gain an efficient antenna can have. A dipole in free space produces a field strength about 2 dB greater than this in some direction; an isotropic source over ground produces a field strength 3 dB greater. So this rough estimate of field strength is always lower than the field that a real antenna can produce in some direction.

RF Exposure and You (Hare, ARRL) has some excellent information on how to approximate field strength of real antennas. And of course modeling programs do the same thing. But under no circumstances would I depend on either one, or even better-than-average amateur measurements, to make any determination that might impact human life or safety.

I don't know where you're going to pay "just a bit more" and get anywhere near as much as these folks are promising. As far as US-based companies are concerned, I've been using PCB Express (www.pcbexpress.com). Their deal for a similar basket of features is about $150 for 100 sq in. Being a US company doesn't seem to have made them any better either...the last time I used them, I got 3 defective boards out of a lot of 10.

These guys want $65 for a 155 sq in panel. The next closest deal I know of is Olimex, a European company (www.olimex.com), and they want $105 for a 100 sq in panel. Thats a price difference of 2.5 to 1. I don't care how good they can spell, as long as their quality and delivery are reliable and good.

Personally, for $65, I'm going to give it a try on the next prototype board I send out for fab. I'll let you know how it works out.

Yes, it makes a difference if it's over vs. next to the tuning coil,
because your coupling will change with distance.

No there isn't a set rule (or shouldn't be) -- you should design your
transformer for the desired input impedance of the devices you're going
into, the intended input impedance of your radio, etc., etc.

Ideally you'd decide on what kind of noise & intermodulation performance
you wanted from your set, decide what impedance your 1st stage should
see, and design your antenna coil from that.

Realistically you can just look for similar radios to the one you're
wanting to build and use an average of their input coils as a starting
point, then dink with it if you feel motivated.

> tuneing coil?

There isn't a set rule...it depends on lots of factors in the design,
if you really want to optimize it, and it depends in particular on the
antenna impedance. Since that's a variable, it's not unusual to make
the coupling variable. You can do that by making the coupling coil
rotatable, making it so it can be moved closer or further from the
"tuning coil", or by putting a variable capacitor in series between
the antenna connection and the link ("antenna") coil.

If you lower the coupling, you will have a higher loaded Q and
narrower bandwidth, up to the limit of the tank coil and whatever is
loading it. Some of that can be a good thing, but too much makes
tuning too touchy, and for AM broadcast work, could even reduce the
bandwidth of the received signal, if you use a high Q tank coil. If
you couple too tightly, you can get too broad a response.

Cheers,
Tom

> tuneing coil?

==========

There are no rules except normal network analysis rules.

The generator is the antenna with its internal impedance Ra - jXa.

Generator volts is field strength times effective height of antenna.

The primary coil has optimum inductance when it resonates with -Xa.

The secondary coil inductance resonates with its parallel tuning capacitor
at the same frequency.

The coefficient of coupling beween the two coils is set to its optimum value
of -

K = 1 / Sqrt(Q1 * Q2) or somewhat greater.

where Q1 is the primary circuit Q taking antenna resistance Ra into account,
and Q2 is the Q of the secondary circuit coil.

So everything depends on frequency, antenna length, ground loss resistance,
coil Q, coupling coefficient, and value of tuning capacitor. The
calculations are quite simple.

For the medium waves and a 40 feet antenna, the primary coil has a
wave-winding of many turns spaced a little apart from the secondary coil.
The coupling is fairly loose, K about 0.1

The secondary coil is wound on the same former and is usually a
single-layer, high Q solenoid. But everything is very non-critical and
almost anything will work. Over the wide medium wave band it is impossible
to keep anything near optimum. Just find some wire and start winding.

To do this, one needs a minimum of three triodes, the top pair
being (essentially) a differential amplifier, the bottom being a
configured constant-current source replacing a moderately-
high common cathode resistor for the differential pair.

That's a LOT of circuit work where a single dual triode could
(and has) work just as well. Connect it as a differential pair
and put the signal in one side, the LO in the other.

Any valve that runs its control grid into the positive region is
going to be operating in a non-linear region and will therefore
"mix" well enough to do some heterodyning.

The name "Gilbert cell" got there in later integrated circuit
times to describe a particular arrangement of BJT junctions
to do mixing or AGC actions. Valve circuitry had other
names and worked for decades as mixers quite will without
fancy names. :-)

I've simulated a few tubes just by making a dependent constant-current source for the plate plus a fixed resistor for the plate resistance in parallel to it. The dependent constant-current source would be referred to the voltage across a resistance or other component (see the particular SPICE program). That assumes linear amplification in the tube.

If there's a real need of simulating full plate characteristics, you would have to get a SPICE package that lets you describe the plate characteristics as an equation and then plug that equation into the net list. Not at all easy and you would need old tube datasheets.

Those same old tube datasheets would yield gm and rp for a particular supply voltage and that can be used for small-signal amplification in pencil-and-paper plus calculator "analysis." Figure the rp as a fixed resistance with the RF plate load and the gm as the constant current across that entire RF load. Voltage amplification is then the product of gm times RF load.

But the "Gilbert Cell" mixer also got by for a good long time without
the fancy name.

Nobody used the term in the early seventies when the MC1496 came along.
It was just a double balanced mixer. It was the late eighties when I
started hearing the term, in reference to the NE602, though suddenly
decades of the same circuit was suddenly a Gilbert Cell.

I know I mentioned this at one time in one of the newsgroups, and
there was an explanation, but I can't remember what it was.

There were also some tv tubes used in chroma demodulators
that were sorta 7360 ish. The 6AR8 for one, I know there
were a few others.

BTW you had to use mu-metal shields on these for best
results.

Last time I ordered from Jameco was when they had a closeout sale on
some discontinued parts real cheap.. I got about two dozen CA3028's
intended for a future project. They had cut, formed leads to plug into
an 8 pin dip socket, otherwise prime. The're still in my parts bin
and will probably get used in a rig I'm designing.

As far as computer stuff goes, Jameco is about 2 years behind the state
of the art as far as what they have to sell (anybody STILL building
Pentium II computers, you can get your mother boards at Jameco!).

And if you're going to design anything new, the 7360 is on sale for only $27 a pop (down from $49!) while the 6AR8 is about $5.

Four diodes and a couple of ferrite cores, on the other hand...

Some time ago, Barrie Gilbert, for whom the "Gilbert cell" is named, gave a talk at a local ham club. He began by showing a copy of the patent for the "Gilbert cell", and emphatically pointed out that his name isn't on it. As he explained, he didn't invent the circuit nor did he have anything to do with its invention. At the time it was patented, he was an application engineer, and he wrote a lengthy article in one of the trade magazines about the circuit and its applications (and giving proper credit to the inventor). Shortly after that, through no action of his own, someone dubbed it the "Gilbert cell". The name stuck, and Barrie has spent the time since trying to straighten out the record -- without success. As far as I know, he gives the explanation every time he presents a talk. Ironically, I don't remember the name of the actual inventor of this very useful circuit -- it's in my notes from that talk, buried somewhere.

Barrie is an engineer at Analog Devices, and the chief designer of many of their advanced analog products. He's an exceptionally talented engineer, a real gentleman, and a humble and honest person. But NOT the inventor of the "Gilbert cell" -- as he's the first one to point out.

So if the Gilbert cell is simply a differential pair on top of a
constant current source, and you are advocating only the differential
pair, then I suppose you are advocating the equivalent of a Gilbert
cell with no current source.

Someone had mentioned that I should be using a silicon diode mixer, but that's
not the point... I want my designs to be all battery tubes (plate 25-60
volt), so that the gear can be portable and also withstand electromagnetic
pulse.

The 7360 and 6AR8 require too much plate voltage.

Now from what I understand, the passive double balanced mixer has the best
port isolation, which makes it superior to the Gilbert cell for avoiding
spurs. On the other hand, the Gilbert cell has conversion gain but is more
vulnerable to spurs. So I wonder if the better answer is to build a DBM in
glass, or the differential pair?

Mike, the etymology of "pickle" in this case comes from the handheld
thumb-operated push-button switch sometimes used to release
bombs and other nasty things in WW2 military equipment. It was
about the size of an unsliced pickle. [or cucumber, but cucumber has
too many syllables to be comfortable as jargon]

E.F.Johnson used a similar pickle-sized PTT microphone on their
"Viking" radios, including a short-lived CB transceiver. I would
imagine the cross-over of WW2 jargon to apply there in a dozen years'
span from the end of WW2 although no one I know has used that term.

I wan't "advocating" anything, just stating generalities.

Mixers MUST be non-linear in order to do the mixing.

>Someone had mentioned that I should be using a silicon diode mixer, but that's

Okay, then use the 1R5 pentagrid and be done with it. That
worked fine for Motorola and Hallicrafters in the old days.

Lacking that humongous EMP simulator, I don't know how you
are going to check the EMP-withstanding qualities you want. :-)

>The 7360 and 6AR8 require too much plate voltage.

I never mentioned those.

>Now from what I understand, the passive double balanced mixer has the best
>port isolation, which makes it superior to the Gilbert cell for avoiding
>spurs. On the other hand, the Gilbert cell has conversion gain but is more
>vulnerable to spurs. So I wonder if the better answer is to build a DBM in

1. You've never outlined the necessity of the double-balance in a
mixer. The non-balanced type has worked fine in the original
WW2 "handie-talkie" and on into the BC-1000 VHF manpack
transceiver and lots of battery-operated consumer radios.
Unbalanced mixers were used in the Korean War era PRC-8
series using subminiature battery tubes. For both the Tx and
Rx sections. Also the PRC-6 handy-talky, also VHF.

2. A balanced mixer of any kind is not necessarily a relief from
spurious responses. The choice of frequencies to mix will do
that...for any mixer type. Note: The intermodulation products
are a different situation and depend on the characteristics of
the mixer.

3. I'm not convinced that "battery tubes" wil "withstand an EMP."
It's become an urban myth that "all solid-state electronics is
destroyed by EMP but tubes/valves miraculously survive."
Not absolutely true...but I can't quibble with urban myths so
I've just met the MIL STDs with attention to detail on the
probable EMP effects which then passed the EMP simulator.

4. Designing a circuit using battery powered, directly-heated
filaments as a differential pair is going to be difficult...unless you
have a separate "A" battery supply for that differential pair.
Since the cathodes ARE the filaments, not separate as in
indirectly-heated tubes, those cathode-filaments are going to
be elevated or, if run near common, will require a "B-" supply
for the long-tailed pair's large "cathode" resistor.

5. Battery packs are almost in the unobtanium category except
for the single, lower voltage variety. You could use DC-DC
converters but those are now all solid-state and that doesn't
meet the "EMP requirement." Electro-mechanical vibrators
could generate the higher B+ (or B-) but those are terribly
inefficient, short-lived, and get bulky with transformers that
must be at low AC frequencies. Primary batteries such as
the carbon-zinc variety don't last long, maybe several years
if kept very cold to slow down the internal chemistry...all those
being made 30 to 40 years ago are now NG.

6. You CAN use techniques for suppressing ESD (electrostatic
discharge) to protect from EMP effects, then go ahead and
work with solid-state devices with some assurance of
surviveability. But, you MUST know the EMP characteristics
and do a thorough design task analysis on every part. Anyone
using battery-filament tubes should do the same thing although
I haven't any idea if anyone has done that.

#chuckle#

Harry Stubbs (who wrote quite a few SF novels using his middle name -
Hal Clement) has had a similar problem. In his 1950s (I think) novel
"Needle", he mistakenly thought that an organism which was taking part
in a symbiotic relationship was a "symbiote", and he spelled it that
way - the correct Greek word is "symbiont".

The incorrect word was picked up by the SF community, spread, and has
gained common use. He formally retracted the incorrect word when he
published the sequel "Through the Eye of a Needle", but his comments
make it clear he doesn't think there's a chance in hell that his
neologism will be replaced in popular use by the correct term.

Hi,

I hope you'll pardon me for putting my reply to your post as of
6/8/2004 10:37 PM here, because my cable newsgroup connection is not
letting me send messages out, its going to look a little out of order.

> Okay, then use the 1R5 pentagrid and be done with it. That
> worked fine for Motorola and Hallicrafters in the old days.

That's a definite possibility. I won't mind using a pentagrid
converter if there is really nothing better for glass.

My question is simply to ask whether "21rst century"
topologies for silicon such as DBM, Gilbert cell, or commutating
mixer might help make hotter equipment than the original designers
of the tubes intended.

However, if all topologies including pentagrid basically deliver
the same performance, than you are right: I should stick with
simple and be done with it.

> Lacking that humongous EMP simulator, I don't know how you
>are going to check the EMP-withstanding qualities you want.

Let's assume that someone living in a city, suburb, or large town
is going to be quite dead if they live in the same range as something
that could kill a tube (unless of course it was a "coldbringer" EMP
warhead). Let's posit that vacuum tubes are still more surviveable
than semiconductors, all else being equal.

But a 1.5 volt "AA" alkaline battery is cheap enough if I need a
seperate filament.

B+ will likely be 4-6 9V alkaline batteries in series... cheap in bulk
at Target.

Anything to which I can apply common sense or overkill to? I can't
possibly
hope for this to be Cold War equipment, I'm only just looking for some
kind of edge.

I agree with everything else, but at RF you can just make a
bifilar-wound filament choke -- you'll be at DC ground but you can
inject whatever signal you want. Since everything is so high impedance
and you want low power you can make it the final inductor in a matching
network, for that matter.

>> worked fine for Motorola and Hallicrafters in the old days.
>
>That's a definite possibility. I won't mind using a pentagrid
>converter if there is really nothing better for glass.

Those and pentodes (such as 1T4) work fine as mixers on
up to 10m in consumer radio receivers such as the Zenith
Transoceanic series...but they are starting to get rare, as
are 7-pin miniature tube sockets using ceramic or mica-
filled plastic dielectric!

>My question is simply to ask whether "21rst century"
>topologies for silicon such as DBM, Gilbert cell, or commutating
>mixer might help make hotter equipment than the original designers
>of the tubes intended.

One has to consider the type of active device as to configurations.
A "Gilbert cell" or double-balanced mixer-multiplier arrangement
is only practical in a single-chip semiconductor package. One
can also make a good operational amplifier out of two dual triodes
as George A. Philbrick Inc. once did under the "GAP-R" model
series. [Bob Pease likes to mention those in Electronic Design
since he once worked there] The sizes of the two, even if the GAP-R
was efficiently packaged, just doesn't compare to a typical 741 op-
amp can.

As to "hotter," let's put it this way: ANY radio can be made with
enough amplification to have the front-end noise come roaring
out the speaker like Yosemite Falls at the collecting basin. The
type of device or the device configuration doesn't matter...but the
bandwidth and the first device's inherent noise generation does
matter. There is some information on indirectly-heated tubes'
inherent noise generation in some older textbooks but I didn't
look at a sampling to see if directly-heated filament types are
included.

I once had a nice Hallicrafters "all-band" receiver using battery
tubes, bought in a PX about early 1955. After military days that
became a trial device for modifications and other ideas. With
some changes in the Ls and Cs in the front end, it could do a
2 uV sensitivity at 6 KHz BW with a 10 db Sig:Sig+Noise ratio.
Not terrific, of course, compared to modern solid-state receivers,
but adequate for SWL with its built-in telescoping whip antenna.
1T4 RF amp, 1R5 mixer, single conversion originally.

>However, if all topologies including pentagrid basically deliver
>the same performance, than you are right: I should stick with
>simple and be done with it.

Actually, the Dan Tayloe design for a DC receiver front-end has
got to be the simplest. It can handle keyed CW and SSB right
off and the CMOS switch used as the "mixer" should be able to
handle large overloads of RF or broadband pulses, etc. What
you now have to contend with is low-noise audio amplification
following the mixer and (if used) the polyphase filter in between.

>> Lacking that humongous EMP simulator, I don't know how you

Posit what you will. If the community is killed off, there won't be
anyone to operate anything that survives the initial blast. Moot.

>> 1. You've never outlined the necessity of the double-balance in a
>> mixer. The non-balanced type has worked fine in the original

>> that...for any mixer type. Note: The intermodulation products
>> are a different situation and depend on the characteristics of
>> the mixer.
>
>okay...

There does exist information, rather detailed TMs on that old stuff,
from rare sites like August Johnson's fine collection of PDFs of
boat anchors (free download and he says he will come out with
CDs to order - small charge - for surface mail later). For slightly
newer stuff, like the PRC-25 and -77 VHF portable transceivers

and the current HF transceiver, PRC-104, the www.logsa.mil site
has some for distribution (a devil of a time trying to find their CD
listings but some files are downloadable by anyone). Those newer
radios are solid-state in the receiver front-ends.

>> 4. Designing a circuit using battery powered, directly-heated
>> filaments as a differential pair is going to be difficult...unless
you
>> have a separate "A" battery supply for that differential pair.
>> Since the cathodes ARE the filaments, not separate as in

>> for the long-tailed pair's large "cathode" resistor.
>
>But a 1.5 volt "AA" alkaline battery is cheap enough if I need a
>seperate filament.

That brings up DC power control. Two many different batteries means
multi-pole power switches plus adequate bypassing of elevated A+
supply lines.

>> 5. Battery packs are almost in the unobtanium category except
>> for the single, lower voltage variety. You could use DC-DC
>> converters but those are now all solid-state and that doesn't
>> meet the "EMP requirement." Electro-mechanical vibrators
>> could generate the higher B+ (or B-) but those are terribly

>> the carbon-zinc variety don't last long, maybe several years
>> if kept very cold to slow down the internal chemistry...all those
>> being made 30 to 40 years ago are now NG.
>
>B+ will likely be 4-6 9V alkaline batteries in series... cheap in bulk
>at Target.

Okay, but add up the prices on those 9 Volters...allowing for the
income adjustment and COLA for monies, that sort of series
arrangement is today roughly twice the cost of the (adjusted) price
back in 1960. Primary batteries have taken a large price raising
(because they can) since portable consumer devices began
appearing three decades ago.

>> 6. You CAN use techniques for suppressing ESD (electrostatic
>> discharge) to protect from EMP effects, then go ahead and
>> work with solid-state devices with some assurance of
>> surviveability. But, you MUST know the EMP characteristics
>> and do a thorough design task analysis on every part. Anyone
>> using battery-filament tubes should do the same thing although
>> I haven't any idea if anyone has done that.
>
>Anything to which I can apply common sense or overkill to? I can't
>possibly hope for this to be Cold War equipment, I'm only just looking for

some
>kind of edge.

Okay, then drop the "EMP withstanding" personal specification.
Common sense says: Individual stage shielding and bypassing
anything that isn't an RF/AC signal; have the power switch also
short the antenna input; put in back-to-back switching diodes on all
RF/AC stage-stage lines that aren't handling more than a 0.5 volt if
you must have some kind of EMP withstanding capability.

"EMP" is ElectroMagnetic and is a very broadband impulse. It isn't
juju or magic, just very high level Ultra Wideband stuff. It doesn't
reach in to find out if a circuit has tubes or transistors, selectively
blowing out only the solid-state things. Approach the total design
with this super UWB environment, looking at EVERYTHING that
might pick up the super UWB of an EMP. If you want real
survivability, then get a sturdy metal box with an excellent
conductive seal all around and store the radio in there. Add a sign
telling others what is there since local humans can be fried by an
EMP through their own internal wiring.

Or, just have fun making whatever you want to make, hoping the
powers-in-charge never decide to use an EMP beastie.

in case of a nuke attack (far more likely than an EMP), the valves' shell will shatter. you are better off storing your regular transceiver inside a thick copper box with an 'rf tight' lid.

instead of EMP-proofing the transceiver from inside, EMP-proof it from the outside.

your best bet would be to use a 7MHz CW transceiver with 5 watts output. This will give you consistent communicability with reasonable power to get through. More power will drain your battries (or your legs, if u are pedalling a generator) faster. Avoid FETs and MOSFETs in your design, stick to bipolars. also avoid ICs, use discrete transistors, store a few spares in a bag inside the transceiver. have soldering iron handy too, u might have to repair quite a few things. you will also need an antenna tuner and a long wire.

this is a pretty grim discussion. in 1999, my country(india) and pakistan were on the brink of war. my city was considered a high value target. i have lived these thoughts far too close to comfort. there are no nuclear shelters in india save a few for the president and the prime minister etc. thinking back about those days, i find it ironic that i thought that i would personally survive an nuclear attack and have enough sense left to get on with establishing a wireless station.

Yes indeed, the 1L5 and 1T5 are getting extremely costly.

I had been doing other surfing between our exchanges. I found a duo-triode battery tube, one of those could make a long-tailed pair mixer. I also found a duo-diode plus pentode, and a diode plus pentode. Two of the former tubes could make a 4-diode mixer plus signal/buffer amps on each side. Two of the latter tubes could make a 2-diode mixer pls plus signal/buffer amps on each side.

All very good suggestions, thank you. So if EMP is simply a noise spike from DC to daylight, is it that I should employ traps on all input and output leads to shunt everything outside the band of interest to ground? And the metal box makes sense.

>
> Or, just have fun making whatever you want to make, hoping the

>
> LenAnderson@ieee.org

Um yeah, like I said, this design is for my daughter and her cousins for thier 10th-12th birthdays, with another for myself, so I have at least 7 more years
to get this working.

So how's this for a possible lineup for the receiver?

Preselector: grounded grid amplifier with variable tanks on each side.
VFO: triode oscillator with low voltage neon bulb as regulator and
variable tank.
All three tanks use a single section each of a 3 section variable capacitor.
Converter: duo-triode differential amplifier as mixer.
IF filter: Crystal lattice filter, 8 Mhz IF, 3-6 khz bandwidth
Detector: single-tube regenerative detector fixed to 8 Mhz with +- 6 Khz
tuning through a small variable capacitor added to the capacitor
in the 8 Mhz fixed tank. Also has a manual regeneration control.
Audio amp: standard OTL implemented with battery tubes.
Output to 1 Watt speaker.

In theory, the IF filter with the 3-6 Khz bandwidth provides me with a window open either to SSB or CW. The fixed detector would allow me to receive either SSB or CW depending on the setting of the regeneration control. The detector would be 'tweakable' +- 6 Khz to provide some degree of passband tuning against the IF window.

Now the transmitter:

I have a novel idea for the CW transmitter to reduce the size of the final amplifier tube and the heat dissipation. Implement the final as a high frequency pentode or beam tetrode wired in triode mode, running as class E. I could possibly take that type of battery tube meant for 200 mw IF amplification, and run it at 5 watts class E without much great harm to the tube.

Anything I am missing with this lineup?

Farhan,

I saw your post re nukes on my personal account new server but can't post out, and I don't see your post on Google yet. I hope you don't mind my answering your second message here.

I understand what you mean about the India/Pakistan conflict. I really don't know what to say. Yes, it is a grim business. But I'm thinking about the kind of world my daughter will inherit, and I want her to be equipped for it.

I think that an attack meant to wipe out a country will simply not happen, thank gawd, because the balance of terror still exists today and that balance works just fine. Thats why India and Pakistan came to thier senses, and that's why the US and USSR shadow-boxed each other without doing anything serious.

The only likely scenarios I see are two-fold:

1) Terrorist sneaks in by motor boat or rogue sub to the seashore, walks into a major city with a 50 kilotonne warhead in a backpack and ignites it kamikaze style. The city is wiped, the suburbs are fried, and the farm and ranch country gets hit with the EMP. It's the people in the farm and ranch country that would be in the best shape to use my design and coordinate with FEMA
about how to handle the survivors and the damage.

2) In response to our conventional defense of Taiwan when China inevitably loses patience and invades, China fires a single large coldbringer warhead in the ionosphere above the center of the continental US. The purpose of a coldbringer is not to ruin a city, although it still might very well do so. It is to generate a large EMP across the country to ruin a country's ability to communicate or compute, thereby ruining thier economy and ability to mobilize anything larger than a single army or marine division for some period of years.

It is most likely the unwritten policy within members of UN Security Council that a massive retalitation will never be made in response to the detonation of a single warhead. China would likely say: "oops, so sorry, it was an accident, some general had an itchy trigger finger. We'll execute him and make reparations.". Plausible deniability. In the meantime, our country is powerless to defend Taiwan because while our teeth might be there, our supply lines still originate in the US. China then conquers Taiwan with ease.

In a scenario like this, the entire country will be physically unharmed but will be in chaos, needing operators with equipment not damaged by EMP. I'd like my daughter to be able to help out if she can.

That's all I have to say for tonight.

The Eternal Squire

The fundamental sweep range cannot be extended up to 144MHz because the
DDS won't go that high.

Very accurate narrowband swept measurements can be made using a
"transverter" adaptor, which is under development. The DDS is
up-converted to the measurement frequency, using a conventional mixer
and a stable LO, and the response from the DUT is down-converted.

Broader-band swept measurements can be made by overdriving the detector
and using harmonic responses (with but with some obvious risks of
spurious responses also).

Don't try to make it small.

Arrange the RF/IF components in a straight line, not bent back on itself (to
avoid feedback/oscillation).

Use a metal chassis - unetched PC board is a good material.

If you have built a DC Rx, you could always convert it into a superhet by
adding an IF strip, filter, mixer and oscillator.

Build it as small modules - RF/mixer, oscillator, IF, etc. Start with the AF
amp and work back towards the front end. Try making it for AM first with a
diode detector, then add a product detector and BFO.

For lead-acid chemistry? Have a look at the TI UC3906 data sheet and the ap note for that part. You just need to provide the pass controller capable of 20 amps. I've been toying with using that part to control a switching circuit to keep efficiency high and power dissipation low, but haven't actually tried it yet. The controller IC does a good job, though. I've used them in lower-power linear-pass circuits.

Cheers,
Tom

I don't know how much time they have you spending in the lab, but I home
you get _some_. Some lab work is essential, if for no other reason than
to bring to you, as forcibly as possible, the fact that lab work and
theoretical work are two entirely different things. On the other hand
if all they do is train you to be a jumped-up technician then they
haven't served you very well.

What do you mean by optimum?? Do you have an infinite supply of money, or is that one of the constraints? Do you have a license to transmit on some frequencies? How much land area on each end do you have to work with? Do you care how much power you need to use, or do you want to keep it below some level? What other constraints are you operating under that will help you evaluate just what "optimum" means? And what are you trying to communicate? That is, can you work with very low data rates, say one word per hour, or do you want to send television signals or high speed data? (What do you need to communicate, and how long can you afford to wait to do it?)

If you want to be able to reliably communicate at any time and you have enough funds, a satellite based system is likely your best bet. Cell phones, with their built-in antennas and self-adjusting power, should be fine if you are close enough on each end to the required infrastructure. (i.e., let someone else do all the RF work for you if you can.)

If you want a direct earth-based RF link, with no relay stations between, you can do it on either high frequencies or VLF. With VLF, it will take very large antenna structures and high power (many kilowatts), but once you have a working system, it will work pretty much any time. On HF, there will be times when it is impossible to establish a link at any power, and other times when one watt is sufficient. Generally expect to use frequencies between 10MHz and 30MHz, and expect to need a license. (You can be sure that other people will hear your communications.) Because the frequency you'll want to use will change with the condition of the ionosphere (which depends in turn on things such as solar activity and time of day and season), you'll want an antenna system that can accomodate a range of frequencies. It probably would be helpful to have some directionality in the antenna, as you'd get with a Yagi or log-periodic array, but a simple dipole antenna will work under the right ionospheric conditions.

You can learn a lot about this sort of thing if you read some amateur radio publications. I suppose current editions of "The Radio Amateur's Handbook" from ARRL would be a good place to start.

Cheers,
Tom

Dear Mr. Bruhns:
Yours was a well presented description of the issues attendant to
terrestrial radio communication.
However, Nibiru is a mythological planet that no radio signal can
reach because it is hidden from view.

My research and field trials demonstrated that
using a space orbiting array powered by fusion generators
can produce a temporal distortial.

Once the distortion has opened up, use of a tunneling neutrino
partial beam would be sufficient to transmit the information.

Now to receive it on the other end is another story.

Is that the same as Sitchin's 12th planet? If so, it is
presently supposed to be far, far outside the orbit of
Pluto about halfway through a 3600 year orbit.

Wrong! Geordi used that same method once on STTNG to try to make ice cream once. Didn't work then and never would.

183. "JDM" pic programmer 2

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-13 03:09:31 UTC
From: Ken Scharf <wa2mzeNOTTHIS@bellsouth.net>
Message-ID: <GwPyc.1164$aG5.1093@bignews3.bellsouth.net>
Source record: 25565

Is anybody using the JDM serial pic programmer?
I built the Pic-Programmer 2 version and I'm debugging
it before pluging in a live pic. (www.jdm.homepage.dk/newpics.htm)

It seems that the VPP (MCLR) pin goes from -.6v to +12.87 volts.
I'm worried that the negative voltage (when it should be zero) might
damage the device being programmed. I tried adding a 1n4148 clamp
diode from MCLR to VSS (Anode to VSS) and that brings the 'zero'
voltage down to -.37v or so.

VDD runs +5.11v (exactly what the Zener diode is rated at). The
+12.87v for vpp is about what it should be given the 8.2v and
5.1v zeners plus the drop through Q1 (and that 8.2v zener might
be the low side, I didn't measure the drop across it).

If the slightly negative voltage on MCLR isn't fatal, I guess
the programmer is good to go. Any ideas?

I've used it - it works OK on Win98 but is very unreliable with WinXP, even
with the XP drivers.

Geordi didn't have the right script writers. Any decent writer
would have had him take a hair-pin and modify the food replicator
to create the necessary neutrino beam. Of course, the replicator
would have had to be set to "ice_cream.ben_and_jerrys" to get it
all together.

Hello. Im about 1/2 way through building the simple superhet rx in
doug demaws qrp notebook. (The brown covered one).
It uses a ca3028 mixer ic followed by a crystal filter and 1350 if
amps. Far Circuits sells a circuit board (which i purchased).
the main board is compact..about 4 inches by 3 inches.
Covers just one band..but you can use external converters to cover
other bands.
Let me know ..i could send you some info..jpg files i could scan.
Another good rcvr is the one in the ARRL handbooks ..it uses dual gate
mosfets ..I think its in the early 1990s handbooks.

You may want to check the datasheet for the specific part you are going to
use. the 16F628 datasheet, for example, specifies the absolute minimum
voltage on MCLR at -0.3v. Ditto with the 877 and 84A.

..

I could put a germainium or low voltage drop si in series with
the VPP to block the negative voltage all together. That would
somewhat limit the vpp, which might be a problem.

I added a diode in series with the VPP output from the emitter or Q1
(with the anode toward Q1's emitter) and a second shut diode
from the MCLR pin to VSS (anode toward VSS). Now the VPP voltage
at MCLR swings from -0.05v to +12.6 volts. I hope that's enough
VPP. I may have to change out the 8.2v zener, I measured the voltage
across it and it appears on the low side. I could also just connect
a 1n4001 or two in series with it to raise the vpp supply.

Anyway seems the programmer is safe now. Still need to put a scope
to the PGC and PGD lines and check they are in spec.

I don't know definitively what you need here. A lot of older programmers
went through all sorts of hoops to be sure that value was above 12 volts.
However, lots and lots of folks have success with around 9 or so. I haven't
been able to find a spec, other than the maximum, but Microchip generally
refers to this as "13 volts".

I do remember reading that some pics failed to program if vpp wasn't
high enough. If 13v is the maximum than I must be close enough with
12.6v!

BTW My programmer has a 40 pin socket wired to accept 8,14 and 18 pin
pics in the bottom part of the socket (Device pin 1 9 pins up from the
bottom in all cases) and 28 pin pics in the upper part of the socket
(Device pin 1 at the top of the socket). I have a jumper to remove
vpp from pin 15, and one to set pin 12 at vss for 40 pin pics and
vdd for all others.
So in theory this unit will work with almost all pics.
For the 20 pin units I would need to put a socket into the
socket so pins 10 and 11 can 'hang ten'.

195. 90 degree phase shifter

Hi all,
I'm looking for the element values of the 2Q4 phase shifter as
described in the 1992 ARRL Handbook.
Alternatively, can anyone recommend an active (analog) all-pass that
would give the same or better results. I have some precision capacitors
so that's no problem.
Thanks,
Alan

alan,

the polyphase network used by hans
(http://www.hanssummers.com/radio/polyphase/index.htm) is a very good
idea if you _have_ to use passive components. although hans has used
1% tolerance components, you can get away with even lesser tolerence
and use ordinary capacitors with 1% resistors.

alternatively, you can try using the approach of rick campbell in
using op-amp based all-pass network. these require fewer components
and only 0.01uf capacitors. the resistors can be easily measured on a
digital VOM for precise value and soldered into the circuit. search
the net for R2 direct conversion receiver.

unless you are planning some portable work, an exciting way to do this
is to make your computer do the audio processing work. If you feed the
left and right channels with I and Q, the rest of the receiver can be
implemented in software.

this kind of a receiver can be really simple. an rf amplifier followed
by two singly balanced diode mixers, each followed by a single stage
audio amplifier that will directly feed left and right channels of the
sound card. the rest is software. if you find dsp software to be
messy, you can probably download the freely available software from
www.flex-radio.com and use the ssb modules.

Hi,

> I'm looking for the element values of the 2Q4 phase shifter as
> described in the 1992 ARRL Handbook.

The 2Q4 was an 8-pin plug-in (octal?) and this is how it is shown in the 51SB-B sideband generator schematic.

Pin 1 - 680pF - 487k - Pin 2 - 770k||430pF - Pin 3

Pin 5 - 680pF - 125k - Pin 6 - 198k||430pF - Pin 7

Pins 1 & 5 were strapped and fed with one side of a balanced, band-limited audio input and 3 & 7 (also strapped) with the other. Phase-shifted outputs were then taken from 2 & 6. I guess that 4 or 8 could have been a grounded shell.

I haven't worked it out but wouldn't be surprised if these are not just Wein Bridge values for a certain frequency.

Cheers - Joe

> and use ordinary capacitors with 1% resistors.

Thanks Farhan. I actually used 0.1% resistors, and matched the capacitors also to 0.1% by adding parallel capacitance. Of course, all that could change with temperature due to the different parallel capacitances drifting different amounts.

I believe the passive polyphase network to be superior to the active phase shifting networks which use op-amps. For any given level of component tolerance, a passive network will give much better opposite sideband suppression (I recall seeing 10-20dB reported somewhere but can't provide references). Provided attention is paid to the values used, the network can be made lossless which overcomes any concerns about gain distribution and harming the overall receiver dynamic range.

So the way I tend to put it, is if you _have_ to use active components ...

These days the way to do it would be to use a DSP. If this is for a receiver the DSP would have two A/D converters and a single D/A unit. The DSP would combine the two quadature signals and apply bandwidth filtering. The quadature RF drive to the mixer would come from a DDS circuit with both sine and cosine waveform outputs (AD9853/54).

For a transmitter the DSP would have a single A/D and two D/A stages, and would split the audio into two quadature signals after applying bandwidth limiting and compression filtering.

Having said this, I wish I knew how to write the required DSP software! However I'm sure there are some reading this list with the required skill (talent?). (My software experience lies in other areas, such as embedded controllers, NOT math with imaginary numbers!).

I think if this happened we just might also have an 'oops' and a single
thermo nuke would go off high in the atmosphere above China. "There,
we're even." (This isn't a "massive retalitation", so it's allowed under
UN policy). Now both sides can blindly stumble about in Taiwan.

Yes, a really-nice design, but I just received email from Ashar saying
that he was correcting (LM386 pins 5 and 6 are reversed, for example)
and updating (to make it more sensitive?) the BITX20 article in a few
days, so you might want to wait or contact him directly.

When I modified my PicStart Plus Microchip specified the voltage should be 12.75-13.25. Microchip had a mod to lower the voltage from nominal 13.75 to nominal 13.0 for the newer chips (new about 7 years ago).

alan,

you don't really have to know a lot of DSP to play around with this particular beast. very simply, you collect the audio samples in a first-in first-out buffer of about 250 slots. Each time a new sample is added at one end, a sample is retired at the other end.

each of the 90 degree phase shift-ed samples is generated by simpy multiplying all the samples in the pipe with a individual 'magic' constants and adding them all up together. pretty basic stuff as far as programming goes. the magic constants are themselves quite complex to calculated, but that work has alread been done for you. The CD accompanying EMRFD has those constants in a text file under the DSP folder.

it is really simple. all the controls are soft and you can play with a bunch of things.

if you were considering the analog route, i think polyphase approach is simply the best : it is simple and without any tune-up and the results are on par with the best DSP can offer.

Thanks for the suggestions. I'm reluctant to use the computer as I'm on solar power and can't use the machine for too long, particularly on cloudy days in winter - such as today.
I do have some DSP stuff though - ADSP2100- but as it's fixed point, I'm not sure if it has the precision needed.
I really want to use this an exciter and while filters are probably easier, the phasing method always struck me as more "elegant".

This may be why the 2Q4 network is enclosed in a can. The can may also
be filled with something like thermal grease to keep all the components
at the same temperature.

I found something that I *think* comes close to what I want, but
I am not sure. Look at Figure 7 on the bottom of:

http://laplaza.org/~fvuotto/mustage.html

Assuming I had the correct values for R's and C's for broadband
RF operation, it looks as though I could put VFO on one input and
RF on the other input, getting IF's about 90 degrees apart for
use in IQ demodulation.

Do you all read the same thing that I do?

Thanks,

The Eternal Squire

How about doing an FFT then the inverse which IIRC gives orthogonal outputs?

221. looking for design assistence

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-15 09:03:31 UTC
From: edwgo@evdh.net
Message-ID: <cea56ec4.0406150103.291cf78b@posting.google.com>
Source record: 25503

I'm looking for somebody who wants to collaborate on the design issues related to my new version of Radioscape that will take place in August. I want to improve the electronic design of the transmitters and the receivers. Also I want to experiment with different forms of antenna's.

In the year 2000 I realised my first version of Radioscape for Festival aan de Werf in Utrecht, Holland.
I distributed 12 transmitters over the city center of Utrecht. Each of the transmitters was broadcasting a different layer of the electronic composition that I made for Radioscape. The transmitters were broadcasting DSBSC, all on the same frequency.
The audience could explore the city by walking through the city with a singel signal DC phasing receiver (without AGC!). By walking through the city you mix your own combination of the differently transmitted signals.
there is some documentation on http://www.evdh.net/radioscape.html

For the new version of Radioscape I'm using the orchestra as metaphor for the city. I have made a meta composition for different groups of acoustic instruments. The signal of each transmitter will be corresponding with one of the groups. While your walking through the city you can also say that you're walking through the orchestra.

I'm looking for somebody who wants to advise/collaborate with me on the changes and improvements of the design.
The following issues are important to me to improve:
- The receiver was based on two NE602's and a sense antenna. I'm thinking about exchanging the NE602's for a Tayloe detector (QRP2001) or a R1/R2 based receiver and exchanging the sense antenna for a ferrite rot antenna.
- I've been using horizontal wire based transmitter antenna's (+/- 6 meter) with a loading coil and a (kind of) vertical(!) ground plane. I want to experiment with (multiturn) magnetic loop antenna's with a maximum diameter of 1 meter.
- I've been using the AMP1 (hands kit's) as transmitters because the antenna's were so inefficient. I'm looking for a good transmitter to fit the outcome of the experiments. I guess much less transmitter power is needed.
- The frequency I'll be using is 1,725 mHz with a bandwidth of +/-15kHz.
- In case the collaboration goes beyond the role of just advising there is some money available for compensation.

I'm looking forward for reactions!

kind regards,

Edwin van der Heide
Rotterdam, Holland
(I'm not necessarily looking for somebody in Holland)

> --Myron.

Hi Myron,
yep, figured out the transposition on pins 5 and 6 of the LM386 - when it wouldnt work! - took me a while to figure it out - a good fault finding exercise!, and got the disused grey matter functioning again - I honestly believe you learn very little from something that works straight off, its when it doesnt you have to activate the (in my case at least) long disused brain cells......

Have built the audio amp and the VFO - both working well. Am doing it modular and troubleshooting each one as I go - next step is IF amps. Did the audio amp "Manhattan" style using the NJQRP pad cutter and wound up doing a PCB for the VFO - not being smart, just trying to learn PROTEL pcb design at the same time hi hi.

Have corresponded with Ashar, he is making noises about a mailing list for the BITX20 constructors - an excellent idea to share ideas/disasters/general stuffing around/triumphs etc in the true spirit of homebrew...(and, dare I say it, Amateur Radio)

225. FET AMP POWER SUPPLY

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-15 17:05:00 UTC
From: Jimmy <Gfender@carolina.rr.com>
Message-ID: <0%Fzc.52132$tH1.1847740@twister.southeast.rr.com>
Source record: 25507

I want to power my FET amp(200W) from a mobile power supply. Amp requires 50VDC. It occured to me that car stereo amps use DC to DC converters that would produce the voltages and currents that I need. Would like information on where I could get parts/information to roll my own. I am particularily intersted in the transformer design and where I could get one already made. This doesnt seem to be something one can get easily as a replacement part.

My first superhet project was a 5 tube AM rx. First was to asseble it on a breadbord and then in the chassis. After assembly on a breadboard things went a little crazy from there. Added rf amp, added ham band converters,bfo, more if stages,crystal filter, Q mult,audio filters,...and so on. After about a year there was very littleof the of 5 tube radio left on the board andI never put this thing on a decent chassis but kept it aound for many years of use.

Second ome was solidstate with each section of the radio built on its own little PC board. Each section was built and tested then added to the radio and retested. Kind of cheated on the radio because the VFO was my shop signal generator. Radio performed well but was never as much fun as the first for some reason.

With those power levels you're probably dealing with custom magnetics.
There's a switcher in the '04 handbook with the right power level, I'd
consider basing your magnetics on that, or at least use the stacked
E-core idea.

Barring that you could try to get your hands on someone's surplus car
stereo equipment, and harvest the power supply section from that. You
may also want to shop the surplus suppliers for DC-DC converters. 48V
is a common telco voltage, there ought to be bricks (or combinations of
them) that would step you up from 12V nicely.

Alan,
Remembering back... there were two common designs. The difference
depended upon the rest of the circuit. I believe it had to do with the load
impedance presented to the network by the rest of the circuit.

==========
A solution could be using an off the shelf 12V-DC to 115V or 230V -AC
inverter with an AC to 48V-DC (surplus) power supply unit from the telco
industry . Perhaps not so elegant and a bit bulky ,but readily available.
The AC to 50V-DC power supply unit can also be readily homebrewed with
standard components .With 115 V-AC input , a surplus 2:1 step down
transformer available from the surplus trade would do the trick.
BTW some time ago at a flea market I bought a 230V to 50V-15Amperes
transformer for equiv. US$ 0.50.....yes it is a heavy beast , !
Perhaps that's why it was available for 50 cents.

Although at a much lower power level ,this is the usual way providing power
to a laptop computer in a motor vehicle.

yes it does. theoretically speaking, Hilbert transform is Finite
Impulse Response filter implmented with a specific set of
coefficients. the FIR itself is pretty simple. just an array of
incoming samples. each time a new sample is inserted, you generate a
new output by running a loop through the previous n samples.

pipe has space for n samples at a time.
HilbertTable has n number of coefficients.

```
for (each incoming sample)
{
add sample to the begining of the pipe, pushing out the oldest
sample from the other end;

ouputSample = 0;

for (i = 0; i < n; i++)
outputSample = outputSample + (HilberTable[i] * pipe[i]);

output the sample;
}
```

This will give you 90 degrees phase shift.

i have written a dsp shell which will read samples from the sound card
and write them back to the sound card. you can get the source code
from http://www.phonestack.com/farhan

Why not install a high power audio and RF amplifier in the car and
feed them from a common power supply, since you can not use those two
amplifiers simultaneously anyway :-).

Take a suitable high power audio amplifier, install a switch over
relay between the inverter and the actual audio amplifier. When the
PTT is pushed, the relay switches the power to the RF amplifier. All
the other time you can listen to the music (or to a QSO) at a high
audio volume :-).

One problem is that the RF amplifier requires a unipolar +50 Vdc
supply, while audio amplifiers usually have a bipolar supply. Running
the RF amplifier from a bipolar supply would require transformer
coupled inputs and outputs and isolation of the circuit board ground
from the chassis.

Some bridged audio amplifiers may have a unipolar power supply or it
may be possible to use only the positive side of a +/- 50 V bipolar
supply (but may require rectifiers with a higher rating).

A simple audio amplifier driven from a unipolar 50 V or +/- 25 V
bipolar supply will produce about 56 or 112 W into 4 resp. 2 ohms per
channel. In a bridged configuration 110 or 220 W into 8 resp. 4 ohms
per channel.

With a +/-50 V supply, a simple audio amplifier would produce 110, 220
or 440 W into 8, 4 resp. 2 ohms into a single channel.

I think that looking at the audio amplifier power specifications (into
various loads) should give a hint of what kind of amplifier voltages
are used and thus limit the number of candidates worth investigating.
It should be noted that even if some amplifiers are rated at 2x100 W
or 4x100 W, it is very unlikely, that the power supply is capable of
delivering more than one channel at the rated power for any prolonged
time.

The audio amplifier power supply RFI filtering may be more or less
nonexistent, so you may have to add quite a lot of filtering.

I'm slowly using a four-foot-square piece that I bought at a hamfest for $20
($25?). Such a piece wouldn't be too easy to ship.

I find hamfests to be the best source; Findlay seems especially good.
Unfortunately, you can rarely find any at the smaller 'fests. Whenever they
are at a hamfest, Far Circuits often has blank scraps at extremely good
prices if you don't need large pieces.

Check your local surplus supply houses. If you have any local
electronics production they'll have bare board (and it's amazing how
many different places have PC board houses -- it's a business that seems
to do well in the boonies).

For example, Cascade Surplus Electronics and Wacky Willies in Portland
OR have them (the Tektronix country store used to, but they spun off
their PC board house IIRC).

It does if the "magic constants" are right. Consider
the complex frequency response of a Hilbert Transformer
and work out the impulse response. Unlike linear-phase
FIR filters, the impulse response of a Hilbert
Transformer isn't symmetric.

There are whole books on the subject. I have a copy
of _Hilbert Transforms in Signal Processing_ by Hahn,
which goes in to all of this in more than a little
detail. The challenge is turning the theoretical
impulse response (which is infinite) in to something
you can realize on finite hardware.

Indeed Hamfests are a good source ,surely on the European continent where
scraps of suitable sizes (for your purpose) are sold for approx equiv US$ 5
to 8 per kilogramme. Lately ugly construction is on the increase also due
to availability of scrap PCB material (usually double sided).

Hi,
Yes, I have tried doing just that, and it works after a fashion, but not always and not usually very well.

The most recent ARRL handbook (2004) says that very special and expensive software is needed to simulate oscillators properly.

Not good.

I hope that you will notify ARRL (or have) about this.

If there are serious deficiencies in the software (regardless of whether it is free or not), then possible users should be made aware of them.

Thanks for letting me know, just in case I try to use it.

Jack W8RAG

I should add, there is one thing (at least) that you have to be aware of
with CM. Wires that look like they are connected may not be. Use
Simulation, Check Pin Connections. This should tell you any pins you think
are connected but which CM thinks are not connected.

A DDS isn't going to have good enough phase noise. The OP is correct in
using a pullable crystal oscillator.

This is a fairly standard circuit -- why not just look in an ARRL manual or one of the many QRP transmitter designs for an oscillator? You can check for phase noise by mixing it with a good (fixed) crystal oscillator, or you can just trust it.

Why do you need such such good phase noise?
An average oscillator will be good enough to measure to -70 dBc or so.
You could use a DDS with a crystal clock - this will have good close in
phase noise (neasrly as good as the clock), though coherent spurs might
be a problem.

Richard

many of those amateur constructions are not very good, just put
together, and if they generate a sort of signal the constructors are
happy without worrying what they sound like. Some of the constructor
have of course well reputation, but ARRL handbook usually don't tell
who have designed it.

and in this case I want a definite low noise construction.

Remember when I built my first of many VHF/UHF beacons made after an
amateur concept I listened to the carrier with R-4C and converter, the
sound was awful, so I decided to built a new 12MHz xtal oscillator
using some practice described by Ulrich Rohde, DJ2LR. The improvement
on 144MHz was increadible, and I later learned that the sound was very
good compared with all sorts of rubbish somebody else used, even on
2320MHz

I'm not sure what the current capability is, but I can tell you
that Motorola DC supplies typically run a bit high for voltage (though
15 seems higher than normal, even for Mother 'M.' How accurate is your
meter?)

> The pass transistors are two M9639 transistors in TO-3 case. I have not been
> able to find a data sheet on these guys. Anybody have any info on them?

Try cross-referencing from the number 48-869639. I just did so,
and found that the equivalent is a 2N3772.

Further digging on that number reveals that it is a 20A 60V NPN
power device (no surprise). Specs are at this link:

http://www.onsemi.com/site/products/summary/0,4450,2N3772,00.html

Assuming that the pass devices are in parallel, I would assume
that you have at least a 20A capable supply. You can, however, call
1800-422-4210, follow the prompts to get to Parts Identification, give
them the HPN number, and ask what the current rating is. They should be
able to tell you, and could also probably provide the part number for a
manual for the unit (which you can then order with a credit card).

Happy hunting.

Well, that's why I suggested verifying it's phase noise with a good
fixed crystal oscillator. I certainly wouldn't proceed without doing
this check -- the nice thing is that unless the oscillators lock
together too tightly you get an upper bound to your phase noise, so you
know when you're doing well enough.

"Solid State Design for the Radio Amateur" has some good (older)
circuits. It's been superseded by "Experimental Radio Design" which
should also have some good ones.

Looking for any kind of information about a kit constructed printed circuit board with the following info on it DAGE CM-334. very well made design. Circuit board mounts everything except power supply and is mounted using the select switch and the zero adjust. Kit is very well made excellent components. Has a older 3 digit readout in the upper left section of the board, the zero adjust is in the upper right, and just below it is the selection switch. Selection switch position are; OFF, mF, and uF.

Thanks!

Jim

That depends on your filter. If you're trying to design a high pole count filter with really steep skirts and you want to verify it's final rejection then yes, you need a low phase noise oscillator. This is probably why he has "low noise" in his title.

can't really see I've got any replies in the wanted direction; If I
wish to measure a receivers ultimate performance I am not interested
in seing something like 60dB selectivity when I am expecting 90dB or
more. Had a discussion with LA8OJ, and he suggested that 6MHz ceramic
resonator might be easier to use than a 15.7MHz xtal, 100kHz tuning
range could be achieved instead of 20kHz. But I suppose it was a trick
to limit the amplitude to improve phase noise of an xtal oscillator

Perhaps, but if you want to verify final rejection, you want much wider tuning range than you're going to get from a pulled crystal. A 100 Hz-wide filter might be -100 dB down at 5 kHz but -50 dB down at 50 kHz, and if you care about that, you need to be able to look farther away from the carrier.

His desire for a narrow-range source made me think he was more interested in shape-factor and ripple alignment than ultimate rejection.

Maybe he can use two different oscillators to get the best of both worlds. A high-quality LC oscillator is actually pretty darned quiet at large offsets from the carrier. I think it was Tom Bruhns, or one of the other HP guys at least, who once pointed out that the old HP 608-series boatanchors were quieter at >100 kHz offsets than the flashy, high-dollar synthesizers that followed them.

The "need" for low-noise RF sources was prompted by the
electronics industry going hot and heavy on cellular telephony
which uses partly phase demodulation and clock recovery
circuits in digital electronics. Because of those particular
markets, "low noise" has become a Big Buzzword.

Whether you have one pole or twelve or whatever, you will
NOT need a specific "low noise oscillator!" The very ordinary
sweep oscillators of ten, twenty, or thirty years ago are quite
fine.

Len,

I'm sorry, but I disagree. Concern with phase noise
in *all* kinds of communications systems really
got hot in the 1970s. Adjacent channel rejection
is limited by phase noise performance. It is presently
the limiting factor in HF receiver performance.
Ham transmitter phase noise can easily be heard
during CW DX contests as a keyed increase in noise
floor.

Measurement of a crystal filter with steep sides
could be compromised by PM to AM conversion
on the slopes.

And in response to earlier posts, DDS synths *can*
give very good phase noise performance, but their
usefulness is usually limited by quantization spurs
unless a cleanup PLL is added.

Hi,

I want to fit a receiving preamp to my 29MH mobile radio which runs a 50watt linear amplifier. My plan is to fit the preamp at the base of the 102" whip and to switch it in and out of the co-ax circuit (when transmitting) by means of relays activated by the mic press to talk button. Can I use any 12v relays, well shielded by copper boxes around them and what will happen to my 50ohms impedance?

As you can see I need all the guidance I can get:<)

Regards
Greg

The limiting factor was, and continues to be, the
receiver front-end noise (usually in the first RF stage
or 1st Mixer, often described by NF or Noise Factor),
the ultimate selectivity (usually done by a quartz
crystal filter). Some things exacerbate the front-end
noise such as cascaded low-gain stages, the second
stage contributing some slight amount of extra noise.

>Ham transmitter phase noise can easily be heard
>during CW DX contests as a keyed increase in noise
>floor.

Whether that is done in contests or not, the "phase noise"
heard is MUCH more likely to be generated by the Xmtr
RF section. That noise is more than likely to be just AM
noise from that transmitter or the AM-type noise from the
local receiver front-end.

I'm at a loss to see where an AM-type demodulator is going
to see a small amount of phase noise or even frequency
noise...a diode or "product detector" (multiplier of signal input
times local IF oscillator or "beat" oscillator) is going to pick up
the amplitude-modulated noise of the distant Tx or the local
Rx front-end. That demod isn't going to be able to "hear" much

in the way of phase or frequency noise.

>Measurement of a crystal filter with steep sides
>could be compromised by PM to AM conversion
>on the slopes.

Perhaps...if the PM or FM was quite large. The actual PM or FM from even moderately-stable L-C oscillators is still quite small even with the large shape-factor values of very good quartz crystal bandpass filters.

I did a bunch of measurements of quartz-substrate SAW filters back in 1974 at RCA EASD which had Very steep skirts, steeper than 9-pole quartz crystal lattice filters. The only reason for concern was the _amplitude_ noise out of the RF generator, solved by getting an HP 608F. [60 to 70 MHz center frequency of the SAWs...608F has a nice amplitude stabilizer] That was better than trying for some averaging of multiple sweeps via a minicomputer data logger-averager which would have done the same thing with a controlled stepping RF synthesizer.

Anyone who cares can find out what the PM or FM "noise" is by simply modifying an FM receiver to tune to an oscillator's output and calibrating the FM receiver in terms of deviation done by a signal generator and frequency counter combination. Since PM and FM are - in theory and practice - nearly identical in terms of sideband content versus deviation. That same setup can also determine what the modified FM receiver's own LO PM-FM is as well as the signal generator's stuff. In actual practice, that PM-FM is so low that it doesn't matter one whit insofar as a basically-AM demodulated HF signal is as far as "phase noise."

Oscillator phase noise IS important with various levels of QAM where BOTH AM and PM are going on. The BER there is a very good indicator of whether or not phase or amplitude "noise" is a culprit and the Eye diagram can show which one is worst. There's lots more already been done on various QAM systems but the subject thread wasn't about digital modulations.

The subject thread was about voltage-controlled crystal oscillators used for filter measurement. With good control to suppress garbage on the (VCO or VCXO in more common terms) control line and some ordinary good (and old) practices in making stable oscillators, plus a wideband limiter stage to damp out the AM as the oscillator sweeps, ain't going to be much of a problem except calibrating the setup.

There are all sorts of frequency-variable RF sources that could be made up for this kind of measurement, nicely described in literature all over the industry, but "doing the numbers" on the theoretical "phase noise" of a particular source is what counts.

The way I see it, after doing a bunch of that kind of thing (besides in the 1974 time frame mentioned) is that the now-touted "phase noise" figures just don't matter for this application.

Phase noise can be a factor in obtaining very precise stats on a local frequency standard. "Allen Variance" and all that stuff (which is described in detail on the NTIS website in one section) isn't going to be needed for rather simple PPM tolerance measurements. This is not PPB tolerances.

Lots of late-WW2 era FM-PM systems were used by the military, notably the TRC-1, -3, -4 VHF radio relay sets using PM through a reactance modulator from an ~500 KHz (?) crystal and then doing something like 96 times (? forget the details, long chain of doublers and triplers) frequency multiplication to reach 70 to 90 MHz output. After all that multiplying, the output modulation was so close to FM that ordinary FM demodulators had no trouble receiving it. Bandwidth went a bit beyond 12 KHz. Nobody talked about any "phase noise" then even though the CF-1 and CF-2 carrier bays were also requiring phase and frequency stability of the radio part.

Oscillator "phase noise" specs got in there in more modern times as terms like Bit Error Rate (BER) and Eye Diagrams entered the scene along with the explosion of various cellular telephony and digital modulations. By that time, roughly the beginning of the 1970s, the ultimate in tuneable receiver sensitivity had already been achieved for HF bands and those receivers were on the market. Sensitivity hasn't really changed since that time for most signals involving AM-type modulations.

For a setup to test filters with very precise frequency control as well as stability of that frequency (in all three AM, FM, PM), a DDS is probably the most versatile RF source. But, some DDSs have unique problems of their own, involving the generation of spurious sidebands. That's an entirely different matter than "low phase noise" oscillators.

Here are a number of useful spec sheets
http://www.kbt-dc-supplies.com/specs.php

Standard Linear supply, you should be able to find an adjustment
to drop the voltage to 13.8 VDC (under load)

2N3771 and 2N3055 are used extensively (pass transistors),
I have used the 2N3772 in supplies as replacement.

I do not remember what the Motorola used for a voltage regulator

Can we presume the frequency as about 29 MHz?

What you propose is quite proper to do but that raises the question
of WHY the need to do it?

It would seem that it would be easier all around to add some
amplification in the radio's receiver, behind its built-in switching
or T/R circuitry. The amount of loss experienced in the 10m
band coax isn't going to affect much unless the mobile is a
double-trailered semi with antenna at the aft trailer and radio is
in the tractor's cab. That coax loss will be there as much on
transmit as it will be on receive...which is to say, very little.

>Can I use any
>12v relays, well shielded by copper boxes around them and what will happen
>to my 50ohms impedance?

Very little will happen to the 50 Ohm impedance if you use most
any common small relays that can handle 50 W of anything (with
enough fudge factors to withstand about 200 W of anything).

Use Ohm's Law of Resistance to find the RMS voltage and current
at 50 Ohms for 50 Watts. Multiply those by 1.414 to find the peaks.
Since the mobile antenna isn't a perfect 50 Ohms, multiply the
peaks by 4 as a safety margin. Those are the breakdown voltages
and current-carrying requirements of the relay contacts. Try to keep
the relay contact wiring to/from antenna and radio's coax as short as
possible.

It would be wise to use a "break-before-make" contact set on the
relays. That avoids having a "one-time-use" preamp circuit where
the transmit RF can wipe out the preamp input. Contact action
can be checked at DC and with a scope to be sure.

First of all, the typical (8 foot) whip isn't going to be at a common
impedance over the whole 10 m band. It's characteristics will
change between different vehicle shapes/conductive surfaces even
if at the same frequency in comparing vehicles. No matter, those
things work okay as they are...work better with some kind of

antenna matching network. Antenna pattern will vary depending
on the vehicle and its conductive surface shape and topography.
That is normal, nothing to be overly concerned about.

Only nit-pickers will get into hissy-fits on antenna impedance and
antenna patterns and so forth. :-)

>As you can see I need all the guidance I can get:<)

We can all help there although this thread might get into a different
direction with nit-picking that is sure to evolve...:-)

Relays are okay to use even if they have (what seems to be) "large"
contact arrangements (of around an inch or two). Some will insist
that such things will mess up the 50 Ohm impedance (of the coax)
but then they probably haven't measured actual mobile antenna
installations in detail, such as the connection between coax and
antenna base. No matter, any relay that can handle 200 W of
anything has contact structures that are about 0.01 wavelength
at 10 m and won't affect the characteristic impedance very much.

What I see as a potential problem is the relay contact making
the transmitter output directly into the preamp input, even for a
few milliseconds. That's blow-out time for the preamp with 50 W
potential output...50 W in a 50 Ohm system equals 50 V RMS
or 71 V peak, current is 1 A RMS or 1.4 A peak. [P = E^2 / R
and = I^2 x R] Relay contacts can operate in about 5mS (reed)
to 10mS (rotary spider-armature) to 100 mS (larger leaf-type
contact stacks). It may be that the transmitter output may not
reach full output in a short time (most probable) but that is an
unknown here.

A protective box for the relay is very good for environmental
protection (think salty water in northern climes in winter) but it
won't help otherwise for RF in this case. A totally-enclosing
ABS plastic box should be fine.

Putting on the skeptic's hat, I'd have to ask why the need of a
preamp? If more receive gain is desired, the safer place to do
that could be in the transceiver itself. The T/R switching is already
there and presumably safe to use as it is.

Hi,

Thanks for the prompt and very helpful response.

I do not know enough about radio circuits to fiddle with installing additional preamps directly into the radio it' self.

I want to improve my reception as I normally travel with a group of other Land Rover owners who also have 29MH radios but they are not as fussy as I am about their installations and in many cases they can hear me but I cannot hear them.

I was thinking of using a double pole double throw relay.

I could fit a micro switch to the mic which activates before the press to talk switch activates the transmitter?

Thanks again
Greg

Hey Greg ;-)

A DPDT relay is what you need, but to simplify things, drive the relay with an RF sensitive circuit. Usually a 1N914 into a 2N2222 will work, with some bias resistors and a delay capacitor of course.

That way, you let the circuit do the worrying for you. You key mike, the transmitter outputs RF, the relay switches immediately to "transmit", bypassing the preamp. You unkey, the relay drops out. If you use SSB, add a 0.5 second delay before the relay drops out.

Google is your friend here. Their are literally thousands of 10M preamp designs and almost as many RF operated TX/RX circuits.

I like vacuum tubes myself. I can post a Nuvistor-based design if you wish, to ABSE.

Even at 10 meters a modern radio should be fine, unless you have an
older rig or one that's got a reputation for being crappy I'd suspect a
fault with the radio or the antenna installation. I'd want to do a bit
of troubleshooting before I went off building modifications to something
that may just need repair.

At lower HF frequencies you can test your receiver noise level pretty quickly by attaching an antenna -- if the atmospheric noise is discernible then you have no trouble. I honestly don't know if this is still a valid test at 10M.

If you can, see if you can swap rigs with somebody temporarily and go driving. If the problem follows the rig then you have rig problems, if it follows the car you have car problems. If you have no problem with your car shut down but the noise level goes up with it running (particularly if you hear the ignition) then you have ignition noise problems. You may have an antenna that's more of a dummy load than a radiator (and receiver).

If you still think you must have a preamp you should have a better time installing the preamp inside the radio than outside -- there will be a spot in the radio that comes after the T/R switch but before the mixer. If the radio already has a preamp then you probably have one of the aforementioned faults, and should be looking at "fix" rather than "modify".

I wonder if anyone here has access to service manuals for HP 8711/2/3/4 family
of network analysers. I could use a little bit of schematic and/or a couple
of part numbers.

Thanks

275. Preserving the "Real" in _REAL_ Ham Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-18 17:50:29 UTC
From: "Airy R. Bean" <ariy.r.bean@lycos.co.uk>
Message-ID: <2jgofkF11i2vlU1@uni-berlin.de>
Source record: 25457
Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew

That which differentiates the _REAL_ Radio Ham from
the CBer-Masquerading-As-A-Radio-Ham is his or her
habit of constructing, modifying and repairing radios. At one
time, the components that he or she was using were the same
components used by industry, but there is an increasing gap -
special purpose chips for which no info is available (or only
available under a commercial NDA) and tiny chips that are increasingly
difficult to deal with, especially BGA types.

The components which we use are those that are man-handleable,
but as these become less and less the one that industry use, their
rarity will increase.

Therefore I suggest that it is time to start hoarding old electronic
components and/or the circuit boards on which they come?

276. Re: Preserving the "Real" in _REAL_ Ham Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-18 18:34:07 UTC
From: M1LCR <rees.a@btopenworld.com>

Source record: 25458
Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew

I think you have a point, here, and a possible business opportunity.

Because, as you quite rightly point out, these components are becoming rarer and rarer. So if someone was to go into business "hoarding" these things, then in 20 or 30 years time, they would have a nice business, supplying the amateurs, with components to keep the "elderly" and classic radio's going. It would be a nice little earner and a way to top up a pension !

So go ahead Mr Bean, fill your house with redundant crap, hoard it for 20 years and sell it on.

After all the majority of license holders in 20 or 30 years time will be M3's or former M3's . You know, CBers who aren't technical.......who can't solder ...who send their rigs back to be fixed !

So go ahead, hoard the crap, and see what happens.

If you are correct in your posts that M3's are not "REAL" Radio Amateurs, then you won't have a business.....if you are wrong you will.

Does this mean you are retracting your comments about M3's ?

(PS, do let me know in 20 or so years if you are right).

Adrian
M1LCR

All those amateurs that is, that are still capable of using a soldering iron ! Or who hold a ticket.
Because in 20 or 30 years time, there may not be many amateurs left, at all.

Hi Tim,

I don't think there's anything wrong with the radio, it is fairly new, I was hoping to snatch the last bit of a fading signal from the ether.

It is a very simple radio, the only controls are channel selection, squelch and volume.

I know, get a more professional bit of kit, but I'm always challenged to try and improve things, which eventually costs more than buying the correct thing in the first place.

I thing I've got the message, don't waste my time:<((

Thanks to all for the help.

Greg

Okay. How old is the radio you want to use in the Land Rover?

For those made since around 1970 in HF use, the sensitivity
of the receiver section is already near optimum. Won't be
much improvement by adding an outboard preamp.

>I want to improve my reception as I normally travel with a group of other
>Land Rover owners who also have 29MH radios but they are not as fussy as I
>am about their installations and in many cases they can hear me but I cannot
>hear them.

Then I would look into the connections and possible corrosion
on your existing mobile antenna mounting. If you are traveling
with others no more than perhaps 10 miles or so distant, your
transmitter output may be enough, even though attenuated, to
break the others' squelch and they could hear you.

Chances are that the receiver of your transceiver is just off-tune
and some alignment is needed. I'd check that first, can be
done on-air, receive only with a friend's transmissions.

I'd begin with the mobile antenna mount and connection to the
coax, even the coax itself. Use an ohmmeter and check for
low but finite resistances there. Take apart the mobile antenna
mount and wire-brush (rotary on a drill is my recommendation)
the conductor surfaces. Some corroded contact surfaces may
look clean but an ohmmeter may show otherwise. If there are
lock-washers there, a dab of silicone grease (the thermal
conductivity grease used on power transistor mountings works)
will cut down on future oxidation. The teeth of lock-washers
assures a positive metal-to-metal contact even with grease.

>I was thinking of using a double pole double throw relay.

No problem there.

>I could fit a micro switch to the mic which activates before the press to
>talk switch activates the transmitter?

I like Tim Wescott's suggestion of using a lower-power relay coil
and detecting the RF from the transmitter first...saves having to
run a line from the transceiver for the PTT coil energization...but
that has a danger in the build-up time of transmitter power output
being faster than the detector-relay switchover time. If so, the
preamp will be fried before the relay has time to switch over.

Nearly all PTT transceivers of any kind have a line already there
inside from the PTT switch. Bring that one out and get an RF
detector to measure the transmitter RF output. Accuracy not
needed here. Use an oscilloscope with a slow time base, say
around 0.1 Sec, with a DC input capability, and compare the
timing of the PTT line and the detected RF output. The PTT
line MUST operate FIRST. With at least 0.1 Sec lag of RF
output versus the PTT line, the relay idea has a chance to work.

To be honest, I would suspect you might have some
misalignment in the receiver front end that's giving the
problem of low sensitivity. An outboard receiver preamp may
not help that condition much.

Use one of these preamps. YOu will have to put it between the rig and amp
as they are only good for about 25 watts. They have the switching built in.

282. FA: Tektronix 497P 100 Hz-21 GHz spectrum analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-18 22:47:30 UTC
From: John Miles <jmiles@pop.removethistomailme.net>
Message-ID: <MPG.1b3d0fedb4a7a4089896c1@news-central.giganews.com>
Source record: 25464
Cross-posted to:
misc.industry.electronics.marketplace,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,sci.electronics.equipment

The 497P is specified for coverage between 100 Hz and 7.1 GHz, but because this late-model unit shares its hardware platform with the top-of-the-line 494AP, I was able to calibrate it for the 494AP's full 21 GHz range. It is basically a 494AP without an OCXO standard and external-mixer jack.

This analyzer is in unusually-clean shape, and includes a cover and set of manuals. It would be a good economical alternative to a 494AP for any RF/microwave experimenters who can live without the waveguide mixer option.

http://cgi.ebay.com/ws/ebayISAPI.dll?ViewItem&item=3822660862

As an aside, this unit has the latest 49x ROMs I've run across (version 9.7 from 1992). The EPROMs were socketed, so I took the liberty of reading them to .BIN files. If anyone needs them to repair their analyzer, drop me an email and I'll send the images to you. These ROMs can support any 49x analyzer of similar vintage, including the 494AP, 492AP, 492BP, 492PGM, 495P, and the 2753-2756 line. (They probably would NOT work in older instruments such as the original 492/494/496 analyzers.)

I just tried these out under Linux by using the Wine emulator.
Works ok, but the selection boxes could be a little wider to see
all the text (could be a wine font issue).

If you feel like posting the source code, I'd be tempted to
try a native Linux port.

Greg

Amidst all the quotes and suggestions, I didn't see an explanation of why people are saying what they are saying. Here's an attempt at an explanation.

There is noise in the air, and more noise at lower frequencies. Meanwhile, especially with transistors, it is easier to get gain at lower frequencies than at higher. Once you can hear the noise, no additional gain is going to help. The signal that was below the noise will still be below the noise, only the noise and the signal will be louder.

At 40 meters, there is so much noise that it borders on impossible to make a receiver that doesn't have more than enough gain. At 2 meters and above, the noise is very low, and gain is hard to get. So hard, in fact, that noise in the transistors becomes an issue. It isn't an issue at lower frequencies. At VHF and above, if you want to increase the gain you need to do it at the first stage, otherwise you will be amplifying the noise in the earlier stages. Furthermore, at VHF and above, coax losses tend to be high, so it makes sense to amplify the signal before it has been attenuated by the coax, and possibly fallen into the internal noise of the amplifier. At HF, coax loss isn't much of an issue (except for antennas operated at very high SWR), so if you would need a preamp, putting it at the antenna end of the coax isn't the big advantage that it is at VHF/UHF.

Now, the reason for a little waffling is that 10 meters is kind of in no-man's land. Band noise is quite low, and it does take some work to get the gain you need. It tends not to be expensive to get that gain, so even

cheap radios will sometimes have enough gain, but not always. Back thirty years ago, it was hard to get enough gain on 10, so many older radios could use a little help. But today, two bucks will buy a chip with ten times the gain you can use on ten meters.

The reason for the suggestion on unplugging the antenna should now be obvious. If you can hear the difference in background noise with the antenna plugged in versus not, then you have enough gain in your receiver that a preamp will do no good. This is a worthwhile experiment, given that you have indicated it is a low end rig. I'm sure you hear "band noise", but if it's a sufficiently low end rig that noise could be coming from inside the receiver. Not likely, but still possible. The antenna experiment will put that question to rest.

The reason for the idea of going into the radio to locate the preamp was simply one of convenience - the relay you need is already there. Unlike at VHF, there really isn't a big advantage to putting the preamp at the end of the coax, so why not mount it near the radio where you already have power and don't have to waterproof it, and taking it a step further, why not take advantage of the relay that's already there.

Oh yes, and if you do build a preamp, don't sweat the SWR bump at the relay. As long as you keep all the connections reasonably short and straight it won't be an issue.

Hope this helps a bit

..

287. FM BCB Rcvr. design...

Newsgroup: rec.radio.amateur.homebrew

Hello fellow radionuts (radionauts?). For some reason, I've decided
to design and build an FM tuner. Just to see if I can make a good one
I guess. A few questions have presented themselves:

-PLL or quadrature (IC) decoding?

-Stereo decoding: single IC or "discrete"?

-Throw in SCA! Why not? PLL?

-Anyone in S Ontario (KW) area?

-I'm still having a hard time figuring out AFC. I can see how I might
do it with a PLL - the DC error voltage being used to pull the LO to
the correct frequency. How was it done in the old days? ;-) If I
could design not only AFC, but also automatic tuning of an RF
preselector and perhaps even an antenna tuner, that would be tres cool.

All thoughts greatly appreciated.

You can also use the signal from a quadrature decoder, whether IC's or
tube -- and there's a clever game you can play to make a gyrator out of
a pin-toad, which is how you pull the LO around if you're doing it with
tubes, etc.

president@whitehouse.gov says...
> Hello fellow radionuts (radionauts?). For some reason, I've decided
> to design and build an FM tuner. Just to see if I can make a good one
> I guess. A few questions have presented themselves:
>
> -PLL or quadrature (IC) decoding?

I can't speak to your own needs and interests, but for my part, coming off a big all-mode receiver project, I would say that my next one will definitely be... DSP-based.

I used the Philips SA604AD in my receiver for both WBFM (broadcast) and NBFM decoding, the former at 10.7 MHz, the latter at 455 kHz. It is quadrature-coil based, easy to use and not too hard to find. All of the coils and filters needed for all FM modes are stock parts at DigiKey. But the SA604AD doesn't decode stereo directly, so that may be an issue for you.

> -Stereo decoding: single IC or "discrete"?

Again, the next time I go through all this rigamarole, the final IF output will go straight into an ADC.

>
> -Throw in SCA! Why not? PLL?

In a non-DSP solution, the choice of PLL-versus-quadrature techniques is usually driven by the need for stereo decoding. You're more likely to want a PLL to regenerate the 19 kHz pilot tone for stereo decoding. This is not necessarily the same stage (chip) that does the FM demodulation. Stereo MPX decoding is strictly a baseband process, regardless of implementation.

I didn't care about stereo support in my application, so a quadrature solution was fine. I don't know much about the mechanics of stereo pilot carrier recovery and channel separation, never having implemented it or researched it in earnest. Google returned http://transmitters.tripod.com/stereo.htm, which at first glance looks like a good summary of the process.

> -I'm still having a hard time figuring out AFC. I can see how I might
> do it with a PLL - the DC error voltage being used to pull the LO to
> the correct frequency. How was it done in the old days? ;-)

Almost the same way. You could think of AFC as a crude FLL (frequency locked-loop). The output of the ratio detectors in the old-school FM

sets had a DC bias that corresponded to tuning error. When the radio was exactly on-frequency, the average carrier frequency deviation was zero, and the discriminator's DC output was centered. Drift would cause the development of a non-zero DC bias in one direction or the other, which was fed back to the 1st LO to steer it back on frequency. (Prior to the widespread use of varicap diodes, this was a rather kludgy process.)

There was no phase-locking effect in an AFC system, because ratio detectors can only be used to compare a single incoming frequency against a fixed tank circuit's center frequency. For a true PLL effect, you need a way to generate an error voltage or current on the basis of the phase difference between *two* signals.

> If I
> could design not only AFC, but also automatic tuning of an RF
> preselector and perhaps even an antenna tuner, that would be tres cool.

My suspicion is that you can dispense with the preselector and just use a strong (high-IP3) front end with a bandpass filter. 88-108 MHz is considered a narrow tuning range these days. :)

DSP would be best.

> -I'm still having a hard time figuring out AFC.

You don't need it if you have a synthesised oscillator.

Also see DL5SWB's 'Mini Ring Core Calculator' at:
http://www.qsl.net/dl5swb/minirk_e.htm

This is a core calculator linked to detailed data on a huge range of
toroids:
* The T-type iron dust range
* The Fair-Rite FT ferrite range
* The Siemens/Epcos/Siferrit range
* The Philips Ferroxcube range
* A very useful section on "unknown toroids" which works the
calculations backwards to find AL and mu-i

It also includes an air-core solenoid calculator.

Michael,
Get a copy of the "Radio Designer's Handbook" by F. Langford-Smith. It's
all about tube technology but pages 1150-1160 in the 1953 edition
(revised '67) give a very good explanation of AFC and how it was done then.

Good luck and have fun.

Hi Group,

How difficult is it to put a balance modulator inside an radio that generates AM to get Double Side Band suppressed carrier? Where can I get a circuit for a balance modulator?

Is it possible that someone listening to a DSB with a USB receiver will not be aware that there is another sideband on the LSB side?

Has anyone is this group ever experimented with DSB?

Thanks to all so far for the various comments. I guess i should have explained my design philosophy for this a bit.

I don't want to do anything fancy, like DSP or even synthesized tuning. But, I don't want to go for a minimalist six-transistor design either! ;-) And I certainly don't want to use a radio-on-a-chip! I do want something of good quality in the end.

I'm looking at the middle road. An LNA. A mixer/LO chip. What comes next is more up for grabs. Maybe I'll protoboard several approaches in parallel to gain the most experience and see which works best. A 1-chip solution (quadrature; perhaps use a better delay than a simple LC). A PLL chip + a stereo chip. And if I get ambitious, maybe a "discrete" stereo decoder design... Fun wow.

Well, you could have done that better by adding more than a one line comment! I mean really. Now go away, think about what you did, and come back and post at least 4 lines of sentence to add to the thread. Then you'll be doing it right! 8^)

> The Uncal light is on. What does it mean?

Usually it means you've selected a resolution bandwidth that's too
narrow for the span; e.g., the 100 Hz filter will be too narrow for use
in a 100 kHz/division span. (If you're a ham, that's like turning on
your rig's CW filter and then spinning its flywheel-weighted dial across
the band as fast as you can. You won't hear anything but a few muffled
clicks if you do that, because the filter doesn't have time to respond
to any signals.)

Turning the video filter off may help, too. It will 'smear' at fast
sweep rates just like the RBW filter.

The sweep time/division switch should be set to "Auto" for 99% of all
measurements with these analyzers. If you set it to a fast sweep time,
the Uncal light will come on. (Make sure this switch works properly; I
had a 492 once that sometimes failed to read the switch at power-up
time.)

>
> Also, the manual for this would be really great.

They are fairly common on eBay. Usually sold on CD as .PDF files (such
as http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=3821468630), but
once in awhile some originals will show up. Tek has kindly released
their copyright interests in the older test-equipment manuals, so there
are a lot of people selling reprints. I don't know this seller and
can't vouch for the quality.

You can also try http://www.manualsplus.com,
http://www.manualmerchant.com, and http://consolidatedsurplus.com.

Thanks.

I'll look at those pdf files on ebay.

The uncal light is unfortunately always on, none of the settings affects it. The controls seem to work, but they don't affect uncal led. I guess I really need the manual. Probably something in there that could explain it.

That would make me suspect the keyboard controller chip. In the 492, I ended up replacing it with a BASIC stamp (which I still have in the junk box somewhere; you're welcome to it if that's the problem).

Does your TIME/DIV knob do anything at all?

Yeah, you are correct.

I should have added more than a one liner.

Next time I'll know better.

Gee, I think I'll have pizza for dinner.

I think I left out a 'www.' on that one. You're right, it's the same
site as usimperio.com.

They have just about every manual on the planet, but the trouble is,
they only rent them. Consolidated Surplus's prices and policies are
very reasonable, but wait until you take a Tek 49x schematics volume to
Kinko's to have it copied. It costs a fortune and they *always* screw
it up somehow, because it's such a complex job.

The .PDF files are a much better deal, if they're legible at all.

If you mean converting an AM transmitter to DSB it may not be trivial if the radio modulates the finals -- generally a DSB or SSB transmitter generates the energy at a low level and amplifies it up with a linear amplifier, while an AM-only rig may very well have a class-C final RF amp who's power supply is audio-modulated.

>-PLL or quadrature (IC) decoding?

Quadrature. Probably double tuned. (One of the old, now obselete,
demodulator IC's had a good description on double tuned quad coils,
but damned if I can remember which one. I searched for it, as there
was a newsgroup discussion of them going on at the time).

PLLs are feedback loops. Feedback loops are driven by error. In this
case error would show up as distortion.

You could also mix down to a lower IF than 10.7 and use a frequency to
voltage converter. (A precision one shot triggered on each cycle).

>-Stereo decoding: single IC or "discrete"?

>-Throw in SCA! Why not? PLL?

Narrowband IF ICs like the MC3361 make a good SCA demodulator. Basically
a superhet using the onboard oscillator and mixer that runs a 455 kHz
IF and a quadrature demodulator.

I did one with the MC3359, and I think it's on my ftp pages
at ftp://ftp.eskimo.com/u/m/mzenier .

>-Anyone in S Ontario (KW) area?

>
>-I'm still having a hard time figuring out AFC. I can see how I might
>do it with a PLL - the DC error voltage being used to pull the LO to
>the correct frequency. How was it done in the old days? ;-) If I

Just about all FM detectors (ratio det, discriminator, quad)
output down to DC (from the offset from mistuning) , which can
then be integrated/lowpassed to create the AFC voltage. On
frequency may be at 1/2 the power voltage for a quad detector, not
zero volts.

>could design not only AFC, but also automatic tuning of an RF
>preselector and perhaps even an antenna tuner, that would be tres cool.

Signal strength is a different signal from AFC. AFC comes after the
signal has been limited, so that's sort of information is lost.

Random comment: Elektor Electronics magazine, the european project magazine, had a fancy FM tuner project about a half a dozen years ago.

I seem to remember some conversions about 30 years ago where another final tube was put in and the grids were fed in push pull and the plates were in parallel or single ended. Forgot where the audio was fed but think it was either the grids or screens. If there is room in the transmitter it was not really that much of a job.

SCA signals are the Muzak, ethnic radio, and library for the blind
signals hidden on narrowband FM subcarriers. 67, 75, and 92 kHz.
There's also digital stuff, pagers mostly.

Good point; he came up dry when I asked him about 497P manuals but he
may well have some for the 496. I bought a brand-new set of 494AP
manuals from him a couple of years ago.

He might have a keyboard controller, for that matter.

I think they are now over $10 each in Ocean State's newest catalog I
just got in the mail!

I saw a web page somewheres showing that you can simulate a dual gate
mosfet with two jfets in series cascade. J310's work well in this
circuit and they are cheap.

What is your reception goal for this receiver?

- High fidelity?

- High sensitivity?

- Adjacent-channel rejection?

- Overload tolerance?

- Low cost?

(or of course, some combination of the above?)

I think the best way to do it will be VERY dependent on what you're
trying to accomplish.

>
> de KJ4UO

Most of the work on DSBsc in amateur circles is about simplicity. They aren't using it for the benefits of having two sidebands, complete with the receiver circuitry to take advantage of it. It is used because it's cheaper than a complete SSB transmitter. And yes, the intent is that you use a sideband receiver to receive it, at which point it cannot be differentiated from an actual single sideband signal out of the transmitter.

Indeed, unless one has a a synchronous detector, it will be difficult to properly demodulate the DSBsc signal unless one strips off the extra sideband.

With SSB, if the reinserted carrier is off a bit, you simply have output that is somehwat shifted in the spectrum. But if you have a DSB signal, if the carrier is not reinserted right in the middle of those two sidebands, the two sidebands will not translate to the exact audio frequency, and the output will be horrible. Strip off the extra sideband, either at the transmitter or the receiver, and it's an SSB signal that the product detector is dealing with.

So decades ago (and likely it's still the case) the reason most times DSB transmitters appeared in ham magazines was because it was simpler to generate DSBsc than an SSB signal. And all of the articles would talk of how the guy at the other end would likely never notice.

As for modifying an AM transmitter, the trick is to find one with a balanced output stage. If you've got two tubes there, likely it can be made into a balanced modulator. And one thing that is forgotten is that it makes no difference whether the signal is generated at a low level and amplified, or generated at a high level. Indeed, in the latter case you eliminate the long string of linear amplifiers.

Current dual-gate MOSFETs like the Philips BF991 shouldn't be difficult to
find. Packages are very small though, the BF991 is SOT243B.

Bill,

if you don't mind going international, J.Birkett of Lincoln has been
advertising the 40673s for ï¿½1.50 (around $2.50?) for the past two months.
Seems a good price to me for a hard to find device. Check out a copy of Radcom
if you can find on over there.

regards...

What puzzles me in that case is why are all of the functions/buttons working?
Yes, even the TIME/DIV works as expected, all positions. Same goes for other
buttons.

When I turn it on it always starts with some strange settings and I need to reset it,
perhaps the EEPROM or RAM has failed over the years. Or I don't know how to
store the settings.

An exceedingly well-written explanation, if I may say so, Len.
You're of course right to suggest the above solution; the only problem
nowadays being the mind-boggling lack of space inside the new
transceivers!
As for the use of switching relays at RF; surely someone must make RF
relays specifically to preserve the 50 ohm characteristic impedance of
most transmission lines? After all, 29Mhz is one thing, but what is
one to do at say 2Ghz??

This guy has obviously written out his original diatribe in
Serbo-Croat and just parsed it through one of those crappy web
language-translator sites where all the grammar gets screwed up and
much of the sense is lost. What it's got to do with us on this group
is still a mystery, however.

Though not if you buy them from MkV in the UK where they want seven
quid! What's that...$11 for a lousy common JFET. Happily they're
readily available elsewhere for a fraction of that ridiculous price.
Yeah, the cascade solution's good if space permits.

<< Where can I get a circuit for a
balance modulator? >>

P.D.-

Many, if not most SSB rigs generate DSB-SC and flter-out the unwanted sideband. Therefore, it may be easier to generate DSB by modifying an existing SSB rig, replacing the SSB filter with a wideband AM filter.

I haven't listened lately, but years ago there was a foreign broadcast station just above the Fifteen Meter band, that was broadcasting DSB-SC. The carrier wasn't completely suppressed, so I suppose this is "VC" or Vestigal Carrier! I think the station was out of Quito, Ecuador.

This station was intended to be received using a synchronous detector. I had no trouble receiving it on my SSB rig. I could even get music to sound OK by careful adjustment to match their frequency.

That's odd, all right. With my 492, I had to manually rotate TIME/DIV
back and forth into the AUTO position after power-up to get the
instrument to read it.

I'm not sure what would cause random or non-standard power-up settings
besides a flaky keyboard controller that doesn't respond to the CPU's
first few accesses after power up. The 496 doesn't have the capability
to store its settings in NVRAM like the 494 and later models, so it
shouldn't be a case of corrupted memory. The EPROMs are checksummed, so
if you don't receive any power-up error messages, they are OK.

I suppose one worthwhile test would be to make *sure* that the UNCAL
light is on for no good reason (as opposed to invalid startup settings).
Power it on, rotate TIME/DIV back and forth leaving it in 5
seconds/division (the slowest setting), and manually set the other
controls for 1 MHz RBW and 100 MHz/division sweep with no video

filtering. The UNCAL light should definitely not be on at that point.
If it is, you can disregard it for the time being if everything else
works right.

I'll poke around in my 492 manual and see if anything leaps out at me.

What sort of project did you have in mind? There
is a reason they don't make 40673s any more, and I
am always slightly suspicious when somebody is
looking specifically for them. At the height of
their popularity, ham projects used 40673 for all
sorts of things. Now, about the only thing people
still do with them is low-noise RF amplifiers
(e.g. BF991).

My supply of BF961/981s came from Cricklewood in London
and Les Cyclades in Paris. Barend Hendriksen have them
too.

Well, that's a pretty extreme oversimplification.

Error above the loop bandwidth shows up as distortion. To use a PLL to
recover FM, you use a wide bandwidth that covers the entire baseband
spectrum of interest. That way, the error *is* the signal. Very
standard technique.

If they are similar to the ones made by the major cystal manufacturers they should have the same pinout. It seems to be standard - Gnd on pin 2, Vcc on pin 4, etc.

Pretty much all of the above. Cost is secondary. Though I do like simple elegance, and I'm not going to go as far as the SUPRX mentioned by Bob, though it must be a fine rcvr.

Mark mentioned:
>>could design not only AFC, but also automatic tuning of an RF
>>preselector and perhaps even an antenna tuner, that would be tres cool.

>Signal strength is a different signal from AFC. AFC comes after the
>signal has been limited, so that's sort of information is lost.

Yes, I know. I was just conceptually linking AFC to "AAT" and "APS". The latter two would be a lot trickier I think since we're not dealing with a monotonic function, but one with a peak. Might need a uP or some overly complex analog circuits...

Speaking of quadrature demods, wouldn't best performance be had by using a 23.3ns (90deg@10.7MHz) wideband delay instead of a single or double-tuned LC. I just found one with 30MHz BW...

Michael

The OSC 48-11C has 4 terminals on the top of a rather large rectangular metal box labeled E1,E2,E3, and E4. The box is 11 cm long by 3.7 cm wide by 5.2 cm high. There are two access screws on the end marked "fine" and "coarse". This module looks almost exactly like an old Motorola oscillator module with a model number of "K1052A ASP06". The difference is the OSC 48-11C is in a steel case while the Motorola unit is in a machined aluminum case with three terminals in the same location labeled E1, E2, and E3. Somebody has already sent me some info about the Motorola unit. I suspect the Motorola unit is a copy of the OSC 48-11C, which I think is maybe a double oven design.

The OSC 91-21 module is in a steel case 5.1 cm square by 1.5 cm high. There are only three terminals in a line by one corner. The center terminal is clearly the case, but I don't have a clue about which one is the RF out and Vcc input, and voltage required. I don't want to "experiment" with the two I have as both appear to be new and never used.

Thank you, Paul.

There are many, many UHF-and-up relays available on the market,
but at a price most of us can't afford for hobby projects.

Those designs, as with UHF+ connectors, are arranged to minimize
the literal discontinuities that change spacing, dielectric material, and
so forth that alter the "characteristic impedance" of the equivalent
transmission line section of the structure. That's the price one pays.

There are some alternatives at lower powers. For an example, reed
relays can be fitted in brass sleeves (non-magnetic anything) and
form an acceptible coaxial transmission line section. Takes a bit of
experimentation to get the "outer conductor" v. inner conductor
ratios correct. I know those can operate to 3 GHz with less than
1.5 VSWR.

A high-environment relay (such as Military airborne) is the "rotary"
type. The magnetic core is attached to a plastic spider, all
arranged to move the spider in a short arc. Fingers on the spider
move low-length contacts welded to the hermetic seal pins of the
cylindrical case bottom. Moving contact length is roughly a
quarter inch, less than a cm. Very low contact-to-case-ground
capacitance, under 2 pFd, any combination. Allied Signal made
thousands of them and that style is still available, but for a
horrendous price, such as US$26 for a 6PDT, new. 2 A, 28 VDC

contact ratings...usually with a 28 VDC coil, but there are variants of that for new designs. Hermetically sealed, those last forever. I have some factory surplus left over from 1957, used in Hughes Aircraft radar sets. Those can be found in various surplus gear and most hobbyists just discard them, thinking they can't use them for anything practical. I've had success using those in RF switching up to 1 GHz with VSWRs less than 1.8:1.

A variation is the "crystal can" low-power relay, again sealed, but contacts seldom go beyond 2PDT. Different contact-move arrangements but the contact lead length is very short, minimum inductance, and very low capacitance to case ground or other contacts. Those have cases the size of an HC-6 quartz crystal unit, some slightly larger but in the same dimension ratio.

Even the open-frame, leaf-spring contact arrangement can be used at UHF with minimum discontinuity for balanced line switching. Those require much examination as to the relative spacings of the contact leaf springs, leaf widths, etc., and some are the wrong dimensions and cannot be used. That kind of relay was never designed for RF applications so there are no manufacturer's ratings for that...one has to experiment.

For very quick checking of what can work and what can't, a TDR or Time Domain Reflectometer can show that immediately. TDRs have been around for three decades but are still horribly expensive. Those who have them at work have an advantage of sneaking in experimentation during lunch hour. :-)

Probably not, unless there's something I'm missing. You don't want a wideband circuit here -- the quadrature detector takes advantage of phase shift through the passband. Basically it uses a mixer to compare a signal with a phase-shifted version of itself, with the output being proportional to the actual phase difference. With a single-tuned circuit, the 3 dB point corresponds to 45 degrees of phase shift, and that's where you center the quadrature coil.

I tried it, it all works fine or at least seems to, but the "Uncal" LED is on.

I'm reluctant to open it and see where this LED leads to check the logic.
If it goes to the microcontroller and the port is fried, it won't help me much
anyway. Besides, everything else works at this point. I hope its not an early
sign of something else going to hell later on.

Thanks for your help so far.

All of my older FM tuners have a three-gang "bread slicer", A.K.A. variable
capacitor. It tunes (1) the LO, (2) mixer input, (3) RF stage input. Since
the OP wasn't interested in a synthesized LO, a multigang capacitor would
seem to make sense.

With some imagination, one could arrange a scheme so that the LO would lock
to
a synthesized signal every 200 kHz step. Thus one-knob tuning of multiple
stages, yet with synthesizer stability. Details are left as a student
exercise.

A regenerative receiver by useing one of the gates in the normal way.
And the other is used with a pot to controal the voltage and will affect
the regeneration. The FET is acting like a screen-grid tube or
replaceing the tube.

357. Low current crystal oscillator

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-21 11:52:49 UTC
From: Hans Summers <hans.summers@tudor.com>
Message-ID: <2jo0gjF136mruU1@uni-berlin.de>
Source record: 25389

Hello

I have built 2 very simple 2-chip frequency counters with 8 LED binary readout see http://www.hanssummers.com/radio/sfreq/index.htm . My Mk2 counter is extremely small (just 25 x 16 x 16mm) and consumes a low current of 5mA max.

The question relates to the 4.096MHz oscillator which uses the internal oscillator of the 74HC4060. Of the 5mA current consumption, 1.2mA is used by the LED's when max 7 are on at any one time. About 0.8mA by the diode-resistor gate logic, transistor switch, 74HC4040 and the voltage regulator. Fully 3mA is wasted on the 74HC4060 crystal oscillator + divider. It seems wrong to spend 60% of your current consumption on an oscillator, compared to less than 25% on the LED's.

In the pursuit of excellence in this design, I would like to cut the current consumption of the oscillator section. Does anyone know of a better arrangement that will cut current consumption? Increasing the series resistor wasn't the solution. I put a 100K variable in here in place of the original 2K2. Initially as the resistor was increased the current consumption fell, but at higher resistances the current consumption increased quite dramatically. The optimum was at close to 4K7.

Each sub-circuit in an equipment should be considered seperately, on its own merits, in respect of minimisation of power consumption.

It is essential for the future of the human race that electronic design engineers are familiar with the basic principles involved. Energy consumption has to be paid for throughout life of the equipment. It's a part of the cost of ownwership.

At present much of the world's energy requirements come from oil, gas and coal. Ordinary food is the principal source of energy of course and is always in short supply. Oil is also used to make plastics for the packaging industries, etc.

World war has been in progress for many years about control of food supplies, the oil fields and pipelines. It is becoming daily more intense and building up towards Armageddon. Fundamentally it is a war involving the Multi-nationals, Wall Sreet Bankers and giant Insurance Companies, etc., completely beyond control of World Governments.

Sooner or later the World MUST concentrate on atomic energy. The sensible French already have 90% of their energy requirements provided by atomic power stations. The remainder by hydro-electric and tidal power. The Japanese, having no natural biological energy resources, are also quietly well on their way. Iranians, oil producers themselves, are busy building there own atomic power stations in anticipation of a World oil shortage, but their efforts are sabotaged by multi-national legal and political warfare about who gets the development, investment and construction contracts.

When the World is mainly on atomic energy, electronic circuit designers can feel free to enjoy themselves and exercise their unrestrained imaginations.

Optimistic Reg.

Not familiar with the chips you are using but you should use the lowest
frequency oscillator possible.
Maybe try the 32 + KHz crystal

A lot of the current is used to charge and discharge internal capacity
so doing that less often helps.

Bill, I am aware that CMOS current consumption is dependant on operating frequency. However the simplicity of the design demands a clock frequency which is a power-of-two multiple of 1KHz. Otherwise the counting range would have to be other than 0 to 99.5KHz. This counting range is perfect for amateur bands, the offset off the band edge or next multiples of 100KHz.

In any case the counting frequency of the 74HC4040 in my tests was very similar to the 74HC4060 timebase since I was using an 80m VFO. But the current consumption of the 74HC4040 was negligble. Therefore there must be something about the oscillator configuration which is causing the high current consumption.

That's why I'm wondering if there are other, more power-efficient ways of making an oscillator. Bear in mind that a 32768Hz watch crystal is only 125 times slower than my 4096KHz crystal. Assuming proportionality that's about 25uA. Isn't this rather large for a watch? What sort of capacity are we looking at in a watch battery... 25mAh or less? In this case a watch battery would only last 6 weeks, and that's just powering the oscillator on its own not even worrying about the watch hands.

The problems of how to get rid of relatively minute quantities of mildly radioactive waste materials have been exaggerated by the oil conglomerates and the other multi-national companies in the control of world governments. They do it for obvious reasons via the international media which they also own and control. Whoever owns and controls the Internet will ruthlessly rule the Earth. Only the Chinese can prevent it.

What about renewable sources providing all of it, and sensibly conserving energy with energy efficient appliances, homes, transport etc so that less of it is required in the first place? Nuclear fission of current fuels (Uranium) is in any case only a postponement of the problem since eventually Uranium supplies will be burnt up just the same as fossil fuels.

The real costs of the nuclear alternatives have never been properly considered, since nuclear programs have always been subsidised by governments interested in the defence (or offence) applications of the technology and byproducts. Once the full lifecycle cost of the power stations is taken into account they become rather uneconomic in comparison to other forms of energy such as renewable sources. The latter would have become much much cheaper long ago had they received the same degree of subsidised research and development as nuclear.

At the moment my imagination concentrates itself on the unimaginably tiny and simple frequency counter with tiny current consumption. Forget nuclear, this thing could even run off solar power recharged batteries ;-)

So please, indulge my fancy for an even lower current frequency counter containing just 2 IC's,, and tell me if there's a way!

To get rid of even a relatively minute quantity of radioactive material into
space requires the expenditure of rather huge amounts of fuels. Fossil fuels
that is. Ooops

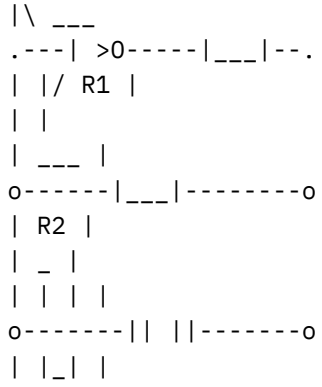
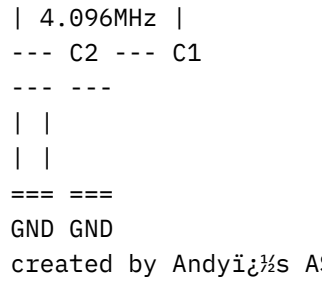
Here's a suggestion. I've never tried this, so YMMV. You're using a
circuit that looks like:





created by Andyï¿½s ASCII-Circuit v1.24.140803 Beta www.tech-chat.de

Yes?

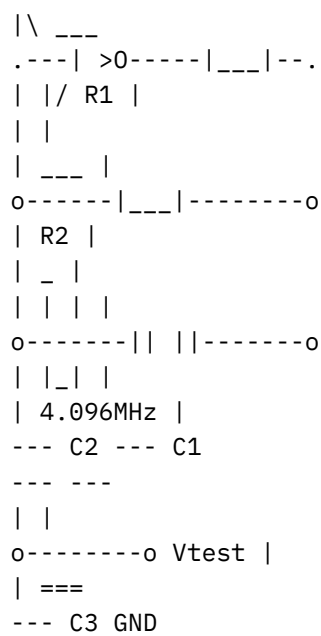
And you've maximized R2 and dinked with the value of R1, and the best you can get is R1 = 4.7kOhm?

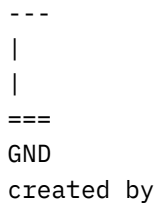
Probably what is happening is that you're fighting two contradictory effects in the circuit: Effect one is that the inverter wants to have a low-impedance output, so a low value of R1 will pull a lot of current from the inverter output. Effect two is that a CMOS inverter is designed assuming that it will be turned on hard; if it isn't then the complementary pair of FETs just conduct current from the VSS rail to VDD.

I think that when you adjust R1 higher you're loading the output less, but you're also supplying less voltage to the input. Your 4.7kOhm value saves you output current, but drops the input voltage enough so that you start seeing more input current.

Why don't you try playing with your feedback a little bit? I'm assuming that you have C1 = C2. If you decrease C2 while increasing C1 so that the series combination of C2 and C1 stays the same the voltage at the inverter input should be stepped up. Depending on about a gazillion factors this may reduce your current consumption.

I would try the circuit below:





Make sure R2 is as large as you can get away with and make C3 about ten times bigger than the crystal's load capacitance, and leave C2 at about the crystal's load capacitance. Now measure the voltage at Vtest (please have an O-Scope!). Because you know C2 and C3 you can calculate the voltage at the inverter input and keep it to 5Vp-p as you play with C1 and R1.

Now play with C1 and R1 and see if you can (a) reduce power even more, (b) keep a good strong signal at the inverter input and (c) keep your desired frequency stability. Increasing C1 should give you more voltage at C2, increasing R1 should give you less. There should be a point where you get good performance at less current than you're getting now.

Phase shift = delay for a given frequency of course. 90deg at 10.7MHz is 23.3ns. Being wideband means the delay and amplitude change over a 150kHz BW are MUCH less than with a single LC. Seems to me that would give the best performance and lowest distortion...

I just tried this with a 74HC04 (no HC4040s, no UHC04s more's the pity).
Best current draw was 1.6mA at 4MHz was with 4.7kOhm and C1 = C2 =
47pF. Then I stuck in a 455kHz ceramic resonator that I have lying
around and Bammo -- 750uA.

So maybe adjusting the frequency lower would be a good thing? Digi-Key
has 32kHz watch crystals.

The 2N3772 is a good chouce for replacement over a 2N3771 or 2N3055.
It has a higher current and higher dissipation spec. Another, even higher
rated transistor is a 2N5886.

Sounds similar to the HPN1003A Motorola supply. Same pass transistors
and voltage. Rated 25 amps out. The output voltage regulator is a 14
volt fixed zener. A 13 volt zener will give 14.2 volts out if it is
the same essential supply as the MITREK. Transformer is part #

A 4060, using National's recommended circuit (from an '80 databook) and
a 32768Hz watch crystal, pulls 32 microamp -- and like I said before,
Digi-Key has 32000Hz crystals in stock, so there's your 1kHz reference.

Now if someone would explain why I bothered to prototype this...

Hi all. I'm doing some serious cleaning. Maybe someone in the Seattle/Everett area would like to pick up any/all of the following:

QST. Feb. 1971 through July 1996, missing Feb, Mar, Apr, Sept 1973 and May 1991.

TS-592/UPM-15 pulse generator. Vacuum tube here. About 45Hz to 10kHz PRF, makes double pulsed with adjustable widths, delay, ... This may be valuable more for the power transformer and the 829 output tube. Last I had it on, it actually did work.

Systron-Donner model 108 solid state pusle generator. Has orig. printed manual. Needs some work in the output stage--should be enough info, incl. schematics, in the manual for a good tech to do this. I could, just don't have time I want to spend on it. Rep rate 10pps to 10Mpps internal, or ext trig to 0pps. Can generate a single pulse, or gated from ext input. 50 ohm output: 0.2V to 50V into 50 ohms. That's 50 watts during the pulse.

TS-403B/U RF generator. Klystron-based generator, 1.8GHz to 4.0GHz. This is the same as an HP something or other...I have a photocopy of the HP manual that will go with it, but couldn't lay my hands on it just now. It oscillates, but I'm sure it needs adjustment per the manual of the repeller voltage tracking vs frequency.

Cross my palm with enough greenbacks and I might ship one of these, but it would not be cheap.

Cheers,
Tom

>everything we throw at it.

There are only two small problems with this approach, since first you have to reach the 11.2 km/s escape velocity to escape the earth. The Saturn V moon rocket was capable of delivering about 40 tons to escape velocity.

With this velocity, you just end up in an orbit similar to the Earth's orbit. In fact the Apollo 10 (or 12) third stage went into solar orbit, but a year or two ago, it was captured by the Moon and Earth and now it orbits the Earth for a year or two, before escaping back into the solar orbit. With some bad luck, this stage might have hit the Earth and imagine that it had contained 40 tons of highly radioactive waste, which would spread into the atmosphere...

Thus, in order to avoid the risk of collisions with the earth in the future, an additional rocket burn is required in the solar orbit to prevent the orbit from intersecting with the orbit of the Earth. Thus reducing the available payload.

If you want to drop something into the sun, you first must kill nearly all of the 30 km/s orbital motion of the Earth. This would require a huge amount of fuel and practically nothing would end up into the Sun.

It is in fact much easier to escape the solar system, since only about 43 km/s is required or 13 km/s in addition to the Earth's orbital velocity. With Saturn V, maybe 500 kg would reach the solar escape velocity directly.

Using Jupiter as a slingshot (as with Pioneer 11&12 and Voyager 1&2) maybe a few tons could reach the solar escape velocity.

Unfortunately Saturn V does not exist any more and the Shuttle and the Proton are toys compared to Saturn V. Any launch failure would also be quite nasty with a lot of nuclear waste on board.

ever since I was a child, magnets have held a fascination for me. I've been collecting them ever since. It used to be that you could always scrounge loudspeakers for Alnico magnets. Then when the newer ceramic magnets began to be incorporated into loudspeakers, it became a challenge to remove them from their enclosures without breaking them. Now, I have to admit, I am having a ball collecting the new 'super magnets' - like the ones inside hard drives. There are also cool cylindrical magnets that you can get from inside the heads of VHS machines. My question is does anyone know of other sources either for Neodymium 'duper magnets', or strong ceramic magnets that I may be missing out on? Magnets like these come closest to being perpetual motion machines we have yet to make, and I'd hate to have some just wind up into the trash because I didn't know they were there :-)

Thanks.!

Okay, well what about dumping it on the moon? Let's face it: there's
not a lot of other suitable uses for this redundant body - other than
providing tidal flows on Earth, of course. I guess you'd get some
complaints from these idiots who've 'bought plots of land' on the
moon, but they're never going to get to build on it in their lifetimes
so WGAS?

Many thanks Tim. I didn't realise 32KHz crystals were available. The usual 32768 wouldn't give the right timing but 32KHz is perfect. You actually prototyped this and measured the current? Did this use an old 4060 or a 74HC4060? What's the difference betweem families in terms of current consumption? Also, how do these families compare to things like 74AC, 74ACT, 74HCT? I know the T means TTL-compatible levels rather than the old CMOS family compatible levels, but is the current consumption different too?

What exact circuit is in your '80 databook? I just had a look at various datasheets from different manufacturers, and all seem to have the same configuration. The national datasheet for the 4060 shows values of 15M and 330K for the resistors to suit a watch crystal http://cache.national.com/ds/CD/CD4020BC.pdf . I also found this 74HC4060 datasheet for the ON Semiconductor version. It includes an interesting treatment of the calculation of the resistor values, see http://www.farnell.com/datasheets/42247.pdf .

Loads of questions I know. But this is fantastic as it will enable me to reduce the current consumption of the thing to under 1.5mA. I hope I'm right in thinking that by replacing the LED switching transistor with a FET, I'll also save some current consumption because of eliminating the base-emitter current, but I'm not a FET expert.

Another nice thing is the 32KHz crystals are physically tiny: 6mm long and 2mm diameter. This means if I use SMD IC's I can make a next generation counter a fraction the size of the current one which is already miniature.
One problem remains, which is getting hold of a 32KHz crystal. I have never bought anything from Digikey. The part I need is XC972-ND and is priced (UK pounds) £0.47. However I notice that there is a £10 handling fee and £12 shipping! The total order cost would be £22.47, for one simple crystal. That's about US $41! Therefore does anyone in rec.radio.amateur.homebrew reside in the US, order frequently or in the near future from Digikey, and wouldn't mind adding one of those to their order and popping it in an envelope to me - I'll pay all costs of course as long as you don't charge me £10 handling ;-)

There is a big magnetic iron core if you dig deep enough.
There are stars with an extremly strong magnetic field,
very very strong.
We need a composite (non metal) spaceship.
hehe

Take apart a hard drive. There is a pail of magnets in the head positioning
servo. They are very powerful and will pinch your fingers if yo are not
careful.

396. help identify: Varian VMC-1680 (5.5 GHz oscillator; Magnetron? Klystron?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-22 13:11:10 UTC
From: peter_dingemans@hotmail.com
Message-ID: <195e9be4.0406220511.557db4fc@posting.google.com>
Source record: 25428

G'day everyone,

A while ago I acquired a piece of equipment, a beacon transponder on 5480 MHz (TX). In it is a 'block' that seems to be the oscillator for TX:

type nr. is 'VMC-1680'
made by Varian/beverly
date code 88236

the sizes of it are 35*55*31 mm; it's magnetic; the output is SMA.

There's a caution on it to keep it at least 4" away from magnets. 3 wires come out of it: red, black and grey. None of them seem to be HV-rated, so my original guess of a Magnetron or Klystron seem to be wrong.

I wonder if it's possible to use it for Ham-purposes (it seems tunable, and the 5,7 GHz hamband is very nearby...)

Anyway, does anyone have ANY info on it? I.e., what IS it, freq. range, power, inputs (voltages, currents), etc. A datasheet would be VERY nice, if it exists... (I already contacted Varian/Eimac (CPII), but nothing came up :-( )
Any help is GREATLY appreciated.

Sincerely,

Peter Dingemans,
The Netherlands.
NB: please also mail any replies to this group to me directly, peter_dingemans@hotmail.com I try to regularly check this group, but only have limited web access.

If it's tunable it can't be a magnetron, anyway, surely? They resonate
at a fixed frequency determined by the mechanical cavities machined
into them.

For purchase:

http://www.gaussboys.com

has a small assortment.

As you are probably aware, the older the drive, typically the bigger the
magnets. The largest that I've found were from an old full-height 5 1/4"
internal 300 MB SCSI drive. Newer drives are a bit disappointing, their
magnets are getting pretty thin and break easily...

Normally I resist the urge to prototype things, but yesterday was slow
and I could do this whole thing on a proto-board. I used a 4060, not a
74xCxxxx device. I have no idea how it'd play out on a xx4060, but with
a 74HC04 and the watch crystal I was seeing 1.6mA, and with the 4060 I
was seeing 32uA. This is an unfair test, because you're supposed to use
the 74HCU04 for oscillators; I have no idea how much this affected
things. I _did_ notice with the 74HC04 that running it at about 3V
brought the current down to the 30-50uA region, however.

It should save a bit, but with a good junction transistor you should
only have to apply about 2-5% of the collector current to the base to
get saturation. If you're using one of the old standbys you should look
at newer transistors -- Zetex is good for this.

The handling fee ($20 in the US) is only applied for small orders, so
you can either get $1.00 worth of stuff for $21, or you can get $21
worth of stuff for $21 -- this still doesn't save you the shipping
charges, though.

403. TS-520 Oscillator Problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-22 17:09:12 UTC
From: Tim Wescott <tim@wescottnospamdesign.com>
Message-ID: <10dgptd685gl900@corp.supernews.com>
Source record: 25435
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I have a Kenwood TS-520 sitting on my shelf with a severe VFO problem.
The oscillator frequency intermittently goes unstable, when the
oscillator doesn't cut out completely. The problem will go away if the
tuning knob is bumped a bit, and it seems to be worse at the higher
frequency portion of a band. The radio is unreliable for receiving, and
is not good enough to even think about transmitting.

Without having ripped into the oscillator yet, I am theorizing that
there is a bad connection on the main tuning capacitor. Before I _do_
tear things apart, I wanted to ask:

1. Has anyone out there seen a similar problem? What did it end up being?

2. The oscillator in this rig is well buried, and will take some
careful disassembly to expose. Do any of you have a manual that details
this operation, or have you done it yourself? I'm well capable of doing
it as-is, but if there's a known best way to do it I'd like to start there.

Thanks in advance.

I just tried it with a 1/2 inch copper pipe and a 1/4 inch cube magnet.
Incredible! I did not know it would have that much of an effect!

Hi,,I am assuming that the VFO in the 520 is very similar to the one in the
TS 820 that I used to own.
The frequency counter did not always work in certain spots on the dial, and
of course the radio went dead at the same time.
I finally broke down and removed the VFO from the radio and opened the VFO
up. The main bearing of the tuning capacitor was not always making contact
because of dried up lubricant.
Don't remember for sure what I did to clean it, I used vaseline to
lubricate and reassembled the whole thing..It worked OK after that..

What a great mental image! I was in need of a chuckle today, and you
came through. Thanks. (BTW, the OP had already mentioned the HD
magnets...)

410. DCF-77 receiver, any ideas?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-22 18:37:45 UTC
From: "Odd Erling N. Eriksen" <odderi@pvv.org>
Message-ID: <cb9u9p$cq6$1@orkan.itea.ntnu.no>
Source record: 25442

Hi,

After getting hold of some nixie tubes, I've built myself an alarm clock using four tubes to show hh:mm (or dd:mm, at the press of a button).

I am now thinking of extending its functionality; rather than keeping track of time using a RTC module, I'd like it to set itself after the DCF77 German LW time signal station.

The format is quite simple - AM, carrier drops to 25% power for a period of .1 or .2 seconds at the beginning of each second, symbolising a logic low or high, respectively. The date, time and other info is then encoded in a datagram whose transmission takes a minute.

My first idea is to build a direct conversion receiver, using a micro-controller with ADC to decode the data stream.

Any other suggestions? Seems DC will get me going with a minimum of parts - all of which I have in my junk box. Any reasons why this might not work satisfactorily? I live on 63'40"N, so the signals are not very strong - my Junghans DCF77 controlled alarm clock works fine in winter, less so in summer. I will be using a much larger ferrite for antenna in the nixie clock, though. Sensitivity shouldn't be a problem.

Thanks,

That sounds very plausible. I got the radio at a hamfest, and I think I
know why...

Did you have any trouble getting the oscillator out, or was it just a
matter of taking the usual care with such things? On my 520 it looks
like I have to go through a few layers to get to the VFO case.

Hi,

The device in question is possibly a YIG oscillator although
there aren't as many wires coming out of it as usual. For a
simple beacon source though (DC power and tuning coil current),
it may not have needed many more.

BTW - magnetrons are/were quite often tuneable.

Cheers - Joe

Not true at all. There are a pile of different tuneable maggies that
were built for Military Uses, in all bands from C, S, clear up thru Ku.
It is just the civilian commercial maggies that are fixed tuned, because
the FCC, DOC, and other regulators don't want untrained operators
messing around with the tuning controls.

Bruce in alaska who used to be one of those regulators......

The magnet moving down the pipe induces eddy currents. These eddy currents produce an electromagnetic force that resists the movement of the magnet (with respect to the pipe) and does so to an extent varying directly with the speed at which the magnet is moving. This slows down the magnet.

At least this is what I have heard.

And aluminum tubes do this also, just not quite as much as copper ones do. And I have seen aluminum tube stock.

Most other metals do this less, but I imagine that iron and lead pipes may slow the fall of a close-fitting "rare earth magnet" a little in comparison to nonconductive pipes.

Strip down an old microwave oven, but be careful of the HV cap, it may
still be charged. (about 1uF at 3000v !!!!) Every one I have found has
a bleeder resistor acros it, so is safe, but you never know.

Anyway, remove the Magnetron and pull it to bits, 2 nice "doughnut"
ceramic magnets await you.

One good way to make a dramatic experiment is to get two identical Neodymium-Iron-Boron magnets, permanently demagnetize one by subjecting it to heat, and comparing how they perform in the copper pipe. You could look up the demagnetizing temperature[1] and rig up a thermometer, but it's easier to hold a small compass near the magnet as you heat it. You could also try degaussing it with a powerful AC electromagnet.

[1] See irreversible demagnetization versus temperature curves at http://www.component.tdk.com/eneor_mg.pdf

100MHz; it has a nice readout of the delay for measuring things like
pulse width and repitition rate.

444. Ic-7800 2nd mixer design question

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-23 20:22:24 UTC
From: hello <hello@nospam.com>
Message-ID: <JCICc.53684$zm5.28054@nntpserver.swip.net>
Source record: 25326
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipement

I have a question about the design of 2nd mixer in the IC-7800.
From : http://www.icom.co.jp/world/products/amateur/7800/index.htm
man could see that Icom use an oscillator with outputs in quadrature and
then sum the mixer outputs after a 90ï¿½ phase shifter.

What I don't understand , is why do they do the 90ï¿½ phase shift in the
analog domain ?
Using 2 mixers with a quadrature oscillator is very common in the DSP
world (IQ demodulation). But in general , it's followed by 2 A/D
converters and if phase shift is needed to reject a side band, it's done
digitaly...
I don't think that Icom choose this design just to save an A/D in the
IC-7800 ....

any clues ?

Hmmm. I haven't studied 'em, but is this an image canceling mixer? I recently ran across an article about them (don't even remember where), but didn't look closely enough to understand it. Probably the same as the phasing method of SSB generation. Now, where the heck was that???...

Back up a bit. What does the current in a loop produce well before the heat
builds up?...

not that you would want to destroy one, but some PMI servo disk motors have six
to eight very large cylindrical rare earth magnets in them. IIRC they are about
1.5 inch diameter by 1/4 inch thick or so. I had one with a bad disk that
yeilded some of these a few years back.

451. Receiving DRM with the DX-394

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-24 00:20:04 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <A1pCc.29959$Nz.1448480@news20.bellglobal.com>
Source record: 25333
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

The DX-394 can be readily adapted to have a 3rd IF at 12kHz to feed a computer sound card with which free software can decode DRM transmissions. Jan Terpstra has designed a two transistor 455kHz-to-12kHz "quick and dirty" converter that he and I have built. Today I successfully received DRM transmissions from Sackville using the DX-394 with the converter and the free DReaM software running on a Celeron 450MHz computer.

The DReaM software is intriguing in its own right and is capable of doing AM and SSB demodulation from the 12kHz IF using DSP. Remarkably, I think it excels the stock AM demodulator at very weak signal reception and provides selectable bandwidth in 1kHz steps from 1 to 15 kHz.

For more on DRM on the DX-394 visit/join
http://groups.yahoo.com/group/RADIOSHACKDX394/ .

This may be an issue of design philosophy.

That stage is doing a conversion down to a very low IF (it's not clear
what frequency from the block diagram), and is presumably low enough that
the image is within the roofing filter passband. Narrowing the roofing
filter might be problematic (because it would limit the available bandwidth,
or because it's too costly to have a narrower roofing filter), but they need
to knock out the image caused by that second mixer. By using phasing,
it attenuates the unwanted image, in the same way that phasing techniques
can knock out the unwanted sideband when generating SSB.

Perhaps they want a linear signal, notice there is an IF stage
after the summing from that second conversion stage, and by doing it
digitally they'd have a digital signal, or be forced
to convert back to analog.

Maybe they didn't want to A/D stages?

From: * <*@*.com>
Message-ID: <2juvg0F162478U1@uni-berlin.de>
Source record: 25335

I have a Varian Reflex Klystron (NIB) has 4 wires 3 out the top one gray out the bottom, with a window in the middle, (unit must drop through a hole in a waveguide?) wires are thick. Takes 2 wires for heater, one for beam and one for reflector (Varian V-152B)
Data sheet has 6.3V heater @1.15A Beam Voltage 250Vdc and Beam Current at 25ma, and reflector at 104Vdc. get a 5.5mW output at ?? frequancy. Varian had a place in Palo Alto Tube Division of Varian Association.

heater wires are yellow, Cathode is green, body is brown and reflector is gray(neg voltage too)

Also have a "Bomac BL820", same kind of wiring, but with a waveguide output, tunable. NOS

Yours - Magnetic means it has a circulator in it, could be a type that gets interrigated.
Magnetic - magnetron?
Some of the bricks take +15 and -12 small bias current, and
ground make 3 wires

Good luck - may be out there. I'm still looking for frequency info on "Bomac BL820", and Varian V-152B

455. XR2206 sweep generator problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-24 04:52:54 UTC
From: stuart.ferguson@adilam.com.au
Message-ID: <7d93334d.0406232052.2436c986@posting.google.com>
Source record: 25337

Hi All...

I am having problems getting the XR2206 from EXAR to sweep with a ramp voltage. I have the XR2206 configured as per fig10. in the datasheet, and I want to sweep from around 975kHz to 1025kHz. (centre frequency 1MHz).

I am sweeping with ramp signal at 33Hz, +/- 2 volts centred on zero, but when i apply the ramp voltage to resistor at pin 7, the ramp is offset by about 1 volt and is distorted. Is this normal? I am only getting a couple of MHz of sweep, way lower than my goal...

What am I doing wrong? Any ideas...?

456. Free: 150MHz mobile FM amp; LM13 freq meter

Newsgroup: rec.radio.amateur.homebrew

Hi all,

More free stuff. Pick up in the Seattle/Everett area, or pay for
packing and shipping:

RCA CT2015 "TACTEC Power Booster" -- 13VDC amplifier for FM service.
Data probably available somewhere, but not too hard to figure out.
UHF connectors in and out.

LM-13 hetrodyne frequency meter; Navy's version of the BC-221. Has
120VAC power supply attached, and has the original calibration manual.
Covers 125kHz to 20MHz (probably useable to 32 or 40MHz; it's
harmonics of the 2-4MHz VFO range.)

Cheers,
Tom

Bugger. Sounds ideal for my harmonic generation experiments. Pity
you're in the States. I guess the shipping would be a bit steep.
Whatever you do, though, Tom; don't throw it away! I rescue old scopes
on this side of the pond and might swallow the shipping fee rather
than see it end up in a dumpster (always a tragedy). How much does it
weigh?

Interesting !!!!! Just downloaded the Dream software and have begun playing with it :) The Drm station I can hear at the moment are not very stron, but managed to get a snippet of things to come I hope !!!. You might also try using th packet output from you PCR. I seem to be able to get partial recognition of the signal from eithe port on the RX. Would ne nice if the software supported the RX though to make at least inital tuning from station view work :)

Are old high voltage components from microwave ovens useful, or should
I chuck them out in the trash?

I have several transformers that look like they are good for quite a
few watts of power, some of the high voltage diodes and several
blowers. I've been saving them.

Can they be used for power supplies for rf transmitters? Are the
blowers any good for cooling large tubes in transmitters?

Thanks,

Al

Good point; he came up dry when I asked him about 497P manuals but he
may well have some for the 496. I bought a brand-new set of 494AP
manuals from him a couple of years ago.

He might have a keyboard controller, for that matter.

-- jm

I still think its not broken since everything works. Except if one of the ports controls
that led
as well.

Some years ago, there was an article in one of the ham mags about converting microwave ovens into high power microwave ham transmitters. It might give some helpful background info. Unfortunately I can't remember the timeframe or which mag ran it. Maybe someone else in the group can remember???

>> can knock out the unwanted sideband when generating SSB.

Yes, it's why man use this sort of design.
But yet again, why not doing the phasing in the digital domain with all
the DSP power behind , it must not be a problem

>> Maybe they didn't want to A/D stages?

Considering the price of the rig , it seems strange.
Perhap's they need vere very very good a/d converter and so 2 will be
too expensive.
Do someone know what do they use as A/D ?
(by the way, it's amusing to see how the marketing speak a lot about the
dsp specs and not the quality of the A/D which is more important and
problematic ...)

They are also built to have high leakage inductance, for current limiting when you put your steel coffee cup in there. This is done by having physically separate windings and a laminated-steel wedge in the window in the core. You have to knock that wedge out.

There was an article in QST or QEX about using microwave parts to build power supplies for linears. Very interesting. Very scary, considering that the author also used old refrigerator drawers as the case...

I saved the pieces from my old microwave in case I ever want to build something that puts out more than 5W.

The software does more than DRM. The bandwidth selection is in AM mode not DRM.

In the AM mode, the Evaluation page of the DReaM software has 15 radiobuttons to select bandwidth. Under the spectral display, a red bar shows the bandwidth selected relative to the demodulator centre frequency, which you set by clicking on the display. For example, if you have tuned the radio toan AM station so that the carrier is at 12 kHz, you see a spike in the display at that frequency. Clicking on the spike centres the DSP filter on it. Then you can vary the filter bandwidth. It's all done in the math in the software.

You can also select USB or LSB, thus shifting the filter to one side of the carrier. Works great on AM with carrier to suppress interference that's one sided. Just think of it as a 3rd IF with variable bandwidth and passband tuning with an AM demod and a product detector - yes you can demodulate suppressed carrier AM too.

73, Tom

A schedule of DRM transmissions is published at
http://www.drm.org/livebroadcast/globfieldtrial.htm . While none appear to
target central Africa, it may be possible to receive others. With your
unmodified radio, tune to the frequencies scheduled and listen for a hash
noise louder than that 10kHz away to either side. If you hear it and it
moves the S-meter a couple of units higher than either side, you will have a
good chance of decoding it.

Regards,
Tom

Well, microwave ovens can run for hours at full power so I guess that
rates continuoue? :) It is true they may NOT be continuous rated at
low or no load due to core saturation.

Tom, thanks for the detailed information. I have used this program many times for DRM and never realized there was an AM option to it. You're right, it's quite impressive what all can be done with this mode. I have a Ten-Tex RX-350 so all the DSP options are already there, but for a radio without these features, this program is great. All interested in DRM or DSP that have a 12kHz IF should try it.

Of course you can use the diodes and the capacitors ;-)
There are some articles on th Internet about converting the transformer for
a spot welder.
A also saw an article on using the magnetron as a PLL like amplifier to put
out 1kw at 13 cm. I can forward the link if you want.

Wim

> case...

Just curious: Do people still build linears with tubes and HV supplies or is it much cheaper now to use transistors? Mine were all tubes but that was about 20 some years ago when FETs and BJT were just way out there in terms of cost.

As one example: Ameritron builds solid-state ham-band amplifiers of up to 600 watts output (their "ALS" series). Starting at the 600-watt point, and going up to the 1500-watt legal limit, Armitron's amps are all based on tubes. There are legal-limit HF amps which use only a single tube (e.g. a 3CX1500A/8877 triode, running at about 2500 volts)

According to a talk I saw recently, commercial television broadcasters have moved almost exclusively to solid-state RF amplifiers for their newer stations. No one set of transistors can provide thenecessary power, so the amps use a large number of smaller modular amplifiers operating in parallel - I think the basic "brick" we were shown was capable of a couple of hundred watts. I haven't seen any ham-band amplifiers using this modules-in-parallel approach, although I'm sure one could be built.

Hi Dave,

Thanks for explaining. 600W is pretty good power already. Since the commercial amps are bricks it seems they must have good protection against sudden mismatches as well.

I remember when I had a coil in the antenna open, which was immediately followed by an exploding coax cable portion. The tubes didn't even flinch but in the 70's just the opening coil would have immediately destroyed even a small transistor amp because the SWR network wasn't fast enough to shut it down.

Regards, Joerg

Every microwave-oven tube has TWO quite-strong cylindrical magnets.
You have to tear the tube apart to retrieve them, but if you'll stack
6-8 of them with opposing poles on a loose-fit wooden dowels with some
kind of stop on the ends, I'll guarantee you that any kid who sees the
toy will practically wear it out playing with it. (Even sitting on
the shelf it looks magical, what with the magnets "floating" in air.)

Several years ago, while driving from Kansas City to Manhattan, KS (about 130 miles) I had an interesting QSO most of the way with someone who said his amplifier was powered by two microwave-oven transformers (two are used because the high-voltage winding is usually connected to "ground" internally).

In broadcasting, the station is usually operating on the same frequency all the time, so simple Wilkinson dividers/combiners (which are frequency specific) can be used, which effectively isolates the modules from each other, when one module fails.

However, a ham linear amplifier is typically required to operate in the 1.8-30 (or -54) MHz frequency range, which complicates the divider/combiner issue.

I suppose this is kinda OT but tubes (usually, klystrons or various modifications thereof) are still generally used for high power at UHF. IIRC solid-state UHF transmitters are available up to about 30kw or so, but larger stations require as much as 110kw to achieve the desired effective radiated power.

Tubes do indeed seem to be a thing of the past at VHF, where powers beyond 50kw are generally not necessary.

I've a FT 480R that has remained unused for at least two years.

Upon attempting to use it today on FM, it displays the TX frequency as 147 MHz. (It is TXing at this freq as confirmed by external frequency counter and dummy load.)

It is RXing quite normally on the simplex channels.

It goes to 147 MHz on TX irrespective of the mode - CW/SSB/FM and irrespective of the RX frequency be it 144.300 or 145.500..

Oddly enough, it does obey the +/- 600 kHZ repeater shift instruction.

Any clues or experience of this problem?

Like other posters, I've gotten some good ones out of some 5"
full-heght 30MB hard drives, and the ceramic donut magnets inside
microwave ovens. There are also some small, moderately strong
(apparently a step below Neodymium) magnets in many small
earphones/headphones (the kind for Walkman type portable stereos with
the 1/8" plug), that I've bought surplus for a dollar each. But some
of these have a little ceramic ring/donut magnet that's about next to
useless.

509. question about cell phone boosters

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-26 22:44:49 UTC
From: Joe <nuisancewildlife@nospamearthlink.net>
Message-ID: <B%mDc.15326$bs4.1771@newsread3.news.atl.earthlink.net>
Source record: 25291

Do cell phone boosters really work, or is it just more hype to get you to part with your dollars? In an area where there are hills and valleys, sometimes I can't get a very good signal in the valleys. It seems like I get calls all the time when I am in an area of poor reception. Has anyone had any experience with these?

Joe

510. Re: question about cell phone boosters

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-26 23:04:01 UTC
From: Jim Pennell <Nospam@killspam.com>
Message-ID: <BhnDc.2101$lh4.1734@newsread1.news.pas.earthlink.net>
Source record: 25292

Cell phone boosters that I know about are all hype.

A cell phone is a low power radio, basically similar to one of the walkie talkies that kids played with. Due to the limited power on Tx, I am amazed they work as well as they do.

Still, they only work when you are more or less in line of sight of one of the cell Tower antenna systems. Surrounded by hills, valleys, or tall buildings, you are usually going to get poor reception.

The so called boosters tend to be flashy metal plates and such which claim to focus the radio waves to get more range. Problem is even if they DID focus the radio signals, which they don't, it would be a directional signal and if you moved the phone away from the exact location, it would lose the signal....

To the group..... I've been having a problem this past week. I've gotten messages cced to me, which appeared as though I sent them, and they were sent to people I didn't know. MY computer is/was being hijacked. While "I" did write the "Message", I didn't write the header. "I" apologize for the below header. It happened in another news group I posted to, at the same time as this message - with a message I posted to that group. I am going to get this checked into. Again, my apologies for the ignorance of the header. While I can apologize for this, I hope my info hasn't been compromised. YUCK! Then I'll really have problems. Not sure HOW to cure this, but I got to!

Hi all,

Free for pickup in the Seattle-Everett area:
==========

RF Design, almost complete from Nov/Dec 1980 to early 2004

Microwave Journal, most issues from May 2000 - June 2004

Applied Microwave & Wireless, mose issues from Winter 1995 to Oct. 2002
==========

These would be too expensive to ship...

They'll go into the recycle about July 1 if nobody claims them.

Cheers,
Tom

You will part with your money. Here is a place to get them for less than $
2 instead of $ 10 or more that is normally asked. Fellows at work ordered
from this place a year ago and got good service from them. The company ,
not the antennas. The other stuff they ordered such as batteries and cases
worked as advertised.

I just got home from Doing My Part at the local club's Field Day site. My part involved taking a receiver out to feed another gyu's RTTY converter, which fed Yet Another Guy's Teletype Model-15, so we could print the ARRL Field Day Message. That was good for 100 points, IIRC.

I was given a 20M dipole to use, strung about 30 feet up between some trees. Tried to copy RTTY on 20M from the dipole, with really cruddy results. A guy offers this Weird Thing with an SO-23k connector. I hook a hundred-foot feedlike to it and put it on a picnic table that far away, and all of a sudden the S4-5 stations are S6-8, and I'm getting _LOTS_ better copy.

Come 0100Z, I get solid copy from that antenna to a disk file on a PC. Just before, we tried the dipole again: cruddy, lots of QSB and QRN.

It's described on <http://www.qsl.net/ka5ruz/>. He calls it the "RUZ" antenna. I prefer to call it the "CPW" antenna: "Can't Possibly Work". But it does. I'm fairly well impressed, folks. You ight want to have a look.

Just you try using one of those 3 transistor CB Radios from the '60's!

Power control is one of the technical achievements of GSM - the mobile
is instructed by the base to lower (or raise) its power appropriately.
Generally,
the maximum power from a handset is 33 dBm (at power level 5) which is
more than sufficient for the 35km wide maximum cell size.

The maximum cell size is determined by the length of the RACH burst.

Are you saying these things are just basically passive horns like you
see used in microwave? "Booster" implies something a little more
active!

Absolutely. It's evident from the simulations I've run that having a
generous lead-length doesn't seriously degrade impedance anything like
as much as the size of the parasitic capacitance does. The value of
Cpar is, it appears, of much greater consequence that attempting to
achieve zero lead length, at up to a Gig at any rate.

Surely any who claims that he is a _REAL_ Radio Ham would know this?

Any why are you operating commercially produced equipment anyway?

We all assumed you limited your equipment to purely home-made varieties
not Far Eastern imports? Surely a case of double-standards old boy,
especially now you've started to befriend a M3 too.

bH.

MEDIA MAIL - OR - MAYBE BUNDLED MAIL (depending on quantity) would be your best approach. It is less than Parcel and so on, but takes a bit longer. You can still insure it (at least media, not sure of bundled) and get a tracker on it. If the parties are willing to pay to ship, why not? At least you'll get rid of them.

I remember the ads for these in PW etc. I wondering what they were. I
assume
some sort of shortened helical dipole with an ATU.

Do you know?

Yes, in fact it was a 6 ft pole with lumped inductance forming the end
loading for the so-called "feeder" , which in reality was a single 30ft
length of insulated wire, end fed from the transmitter via the Joymatch ATU
and tuned against earth.
I understand that due to the highest current portion of the wave being along
this "feeder", with highest voltage being in the lumped inductance, most of
the useful part of the signal was radiated by the "feeder" rather than the
antenna itself!
Nevertheless, the Joystick had its converts in those amateurs who found it
allowed them to operate from locations where normal sized antennas were
frowned upon or lack of space made it impossible to erect.
Whether they ever compared it to an end-fed random length of wire, I am not
sure.

Unfortunately, it's not OK to use that rate for magazines that contain
advertising. See USPS website.

Win wins the RF Design mags...

Please use caution with these ceramic type magnets,
they can shatter and can hurt adults or kids.

Win has the RF Design mags. What's left is the Microwave Journal and Applied Microwave & Wireless. The total weight is close to 70 pounds, and by splitting it into two packages, it could ship for $62. (In a single package, it was some silly amount like $180, because they only do express shipments for heavy stuff, I guess. This is through US Postal Service. UPS would be about $71 for ground service.) Still interested? I'm suspecting it's recycle time for those.

Cheers,
Tom

It is like having a four foot antenna !

Well, not really, this is just wrong.

Besides, your cell antenna is only inches long, having a four foot
antenna (equal to using a 'booster') will get you nothing
the cell frequencies are in the 900 Mhz and higher range.

I got a JoyStick (the pole) and a JoyMatch (the ATU) in 1965 or 1966.
The combination wasn't very effective and performed more poorly than an
end-fed random wire to which I did compare it.

However, my JoyMatch, which I still have, doesn't look anything like
the one on Ebay. Mine is a simple L network tuner, nicely made of a
tapped coil on PVC and a 365pf capacitor in an open configuration
without cabinet. A label on the coil says JoyMatch. I still use it
with an ICOM IC-PCR10000.

Hi Tom,

You are correct about the QST reference. The article is entitled "A DoppleScAnt" by Terrence Rogers, WA4BVY.

The article is very positive about the method.

Your generosity should be much appreciated by someone.

73, Roger, W7WKB

Jim, I've had good luck as well doing the same, but Ovenaire has exchanged
hands several times through the years and had finally ended up with Corning
Frequency Products.

http://www.corningfrequency.com/default.htm

I've contacted Corning at least several times by E-mail and have received
zero response from them. On the other hand I have been very pleased with the
help I have gotten from Isotemp and Vectron. Both have sent me complete data
sheets even on old obsolete products! Now that is customer service.

How do I run an extra power cable through a 1996 dodge caravan's fire wall? I really do not want to drill a hole through the file wall for obvious reasons. I have looked all over the firewall
and cant seem to find an obvious place to run the power cable.

I want to run a high power ham radio and other equimement.

Thanks

Chip Blach

hi chip,

Most of the time you can follow the hood release cable through
the firewall and it will pass the battery on the way to the hood latch.

You can fish the power cables one at a time through the same
gromet the hood cable uses. Little silicone sealer will finish the job.

If you get rid of the car, easy to remove the cable for use later.

Not sure how many amps you will draw, #6 thhn is the minimum
that I use for my two meter rigs. Be sure to fuse them accordingly.

Source record: 25177

Oh, I agree that the power control is a major part of why cellphones work as well as they do....

I was making a point that people need to consider cellphones as relatively short range radios. There is a tenancy to expect cellphones to work all the time, anywhere. But, most radio systems DON'T work that well.

As for boosters, the ones I've seen ARE passive. An active booster system would be fairly expensive. If they really worked, the cellphone manufacturers would have them as an option and just about everbody would own one.

With Ed's link to a manual I think I know how to do it -- it _should_
have occurred to me to take the front panel off!

Now I just need to find the time, and if the bearings _are_ dried out
I'll need to decide what to put back in.

547. C-MAC 1.44MHz BandB. Looking for In-/Out-Inpedance

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-28 06:26:00 UTC
From: Markus Wolfgart <xx_markus.wolfgart@dlr.de>
Message-ID: <40DFB9F8.8060600@dlr.de>
Source record: 25179

Hallo NG,

from my visit of the ham radio in Friedrichshaven, last weekend,
I get some c-mac crystal filters in the hope I could use them for cw.
The filter is labeled as
CMAC EP089.3910
1.44MHz-BandP, B:150Hz
768JAB
Date-Code: 9804 No.: 28654

When trying to match it with 600, 800, 1000 Ohm
by a LC-network (calculated by RF-Sim 99)
(R=600,L=18u,C=618p; R=800,L=21u,C=535p; R=1000,L=24u,C=480p)
I get a Bandwidth of about 300Hz/6dB and the 50-Ohm output
of my HP-Synthesizer goes down to 1/4th of the 10mV I supply
to the Filter and not to 5mV like expected.
Looks like the filter impedance was transformed to about 16 Ohm.
Was my assumption that the filter impedance lies between 600
and 1000 ohm wrong (looks like it was ;-).
When looking at www.cmac.com I was not to able to find any info's
on that certain filter.

Could someone of You provide me the right filter data for the proper
matching.

Many thanks in advance

Media mail doesn't work for (most) magazines because there's
advertising in them. Sorry. -- And for sure I'll get rid of them.
Paper recycle is free here. But I'd rather they go to someone who
would use them, if there happens to be anyone out there like that.
Got rid of about 300 pounds of QST that way on Friday, and got back a
thank-you that the fellow had already used them to look up a reference
he saw on the web.

Cheers,
Tom

I wonder just how many different versions there are? Mine (Joymatch
IIIb) is in a very solid Hammerite-finished case with coloured plastic
covers front and rear. It's just an ordinary L-match inside - although
reasonably well-made. Oddly enough there's no provision for a
ground/earth connection at all on the tuner itself: that must have
caused a few surprises to unwary users in the past :-)

careful, you need an amateur radio licence to operate such a radio. Enquire
at your local amateur radio club or www.rsgb.org.uk for details of
foundation licence classes in your area.

I am trying to buy a few 2sk2975 or the RD07MVS for a fried FT-817.
Can you point to a known retailer?

Thanks

Matthieu

Snake oil.

I suppose the idea is that the booster couples to the antenna, and concentrates the phone's power along the horizon. That keeps you from wasting power shot into outer space, making it more likely that power will reach the base station. Same thing can happen in reverse: by making the antenna more sensitive to signals arriving along the horizon (where they come from) rather than those coming from outer space. (where there are no base stations<grin>)

Problem is... that the design won't work.

The ones I've seen are designed to insert in front of the battery. This location has a few problems:

- The battery, which is mostly metal, shields anything inserted in front of it. Including the booster.

- Any metal in the phone (including the battery, and the original antenna) affects the directivity of the booster - its ability to concentrate power along the horizon. Since the booster is not directly attached to the antenna, the metal in the phone also affects the indirect coupling of the booster to the antenna.

Every phone is different. The size, the shape, how far the battery is from the antenna, it's all different from phone to phone. This means that a single booster design cannot possibly work with every phone. There would have to be a specific design for your phone.

- In any case, the boosters I've seen don't match any valid antenna design I'm aware of. (they really look a lot like the "laundry tickets" we used to use in the dorms at the University of Wisconsin back in the 1970s!) (I wouldn't be too horribly surprised to learn they *are* laundry tickets...)

It is certainly possible to build a cell phone booster. It would have to be custom-designed for your phone. And most users would regard them as impractically large and cumbersome. (probably not eye-doctor-approved, they'd be a serious poking hazard!)

73 to all.
I'm just on this forum for a few weeks and i have already a question.
A friend of mine own an antique FT101ZD (latest model with WARC bands) and his transceiver has a problem.
After a few minutes, the reception stops and the frequency counter displays erratic numbers.
Sometimes, all becomes normal by leaving it OFF a few minutes (or hours).
We think that probably comes from circuits common for TX and RX like VFO or PREMIX, but we are a little lost.

If someone has some informations about this kind of problem, or a logic method to find the solution, it would be very interesting for us.

Hope you can understand my english.
73 and thanks in advance.

Guillaume

First, don't apologize for your English -- as written it's better than many native English speakers manage.

Second, I haven't worked on the FT101, but one basic procedure is to identify a signal that should be there (like the signal out of the VFO) and see if it's there and of the expected strength. If you have an oscilloscope that's dandy, but an RF probe will be enough to make sure that you have signal.

Having a problem that goes away like that is a plus, because you can put your probe on a suspect signal and look for it changing as the radio fails.

It sounds like you've got some component failing due to heat. I _think_ the FT101 is a hybrid, with semiconductors and tubes -- is that right? If so, the problem is either a transistor or diode that's on the edge of failing but works at room temperature, or you've got some other circuit fault thats getting something really hot. Once you find your problem

signal you can start looking for hot components (I use my much-burned fingers), or you can get some freeze spray and look for components that want to be cool.

Good suggestions. I would add that you should find out if it happens on all bands (you didn't say). If so, then the VFO or premixing circuits may be the problem. If you know the VFO frequency you can listen for it on another receiver, with an antenna wire close to the VFO box. You can make a simple RF probe for your voltmeter. Here is a link: http://www.io.com/~n5fc/rfprobe1.htm You don't have to worry about the exact voltage now. Just find out where the voltage drops when the radio quits working. Start at the output of the VFO and follow the signal through. In addition to a part that fails when it gets hot, you may also find a bad solder connection on a circuit board, that also fails when it gets hot. Or the pin on a connector may be corroded (or loose, and bending enough under heat to break the connection). If you follow the signal from the beginning, you will eventually find the place where it stops. Then you know where to look. (Hint: Look for signs of overheating, like a dark place on the bottom of a circuit board.) Bad solder connections are sometimes very hard to see. If you suspect one, you can reheat it and see if that fixes the problem.

The only passive "booster" which would have any hope of providing _some_
benefit would be something like this:

Mount a gain antenna on the roof of your car. Note that this won't work for
hand held units walking along -- unless you made a gain antenna which you
could carry around. Run a coax from this antenna into the car and place
another antenna _close_ to the cell phone antenna. Things like this are
used in tunnels, I believe.Granted, this is pretty "loose", but can provide
some increase in signal both ways.

When demo-ing the very first hand held analog phones a l o n g time ago, we
used such a setup, but needed amplifiers for both directinos in the line
(with suitable filters).

Hello and thanks for reading...

I am seeking a schematic of the TenTec 1054 Regen receiver.

A pretty good search on the net has been met with no success. Have you scanned, or do you know of someone who has scanned this, and would you like to send me a copy?

Of course, a website where this can be found would be just dandy too.

Thanks for any possible help, de WA2AFD

Chip,

Take a *close* look at the rubbery seal/"boot" where the steering shaft comes through the firewall.

On my 2003 Ford Explorer, there was *plenty* of room to cut a small slit with an x-acto knife well below, and out of the range of motion of the steering shaft. I then made sure it was secured out of the range of motion of the shaft on *both* sides of the firewall, going to the driver's side under the hood to the battery (with 25A in-line fuses in BOTH positive and negative leads) and under the carpet to the driver's side wiring channel that runs under the door "thresholds" (which simply snap in/out on the Explorer (the body of the FT-857 is located under the rear, driver's side seat and the control head is mounted on the center console in a good operating position using a Panavise mount I got from HRO ...)

One more hint ... to check out clearances on BOTH sides of the firewall, I used a long, heavy needle probe (about a 3" needle in a plastic handle about 6" long) to probe the spot I thought looked good from a beforehand visual on both sides (the needle punches a small, self-sealing hole, but allows you to see exactly where you are on both sides of the firewall). Then, when satisfied, I used about a 1/2" wide x-acto knife blade to cut a slit (not a hole) that I could push 2 #8 insulated wires through ... a red for positive and a black for negative (it's actually a very heavy-duty "zip cord" that I got from
http://www.powerwerx.com/category.asp?CtgID=1002 (they also have the in-line fuse holders for automotive type fuses, etc.)

Now, this worked just fine on my Explorer ... on your vehicle, YMMV, but I hope the suggestions are helpful.

As well, I found an existing rubber grommet/wire harness pass-thru about
dead center on the firewall that had plenty of extra "skirt". I was able
to use an awl to poke/punch a hole in this extra "skirt" next to the existing
wire harness. After pulling 2 10 ga. wires through my "new" hole, I
slathered some RTV on both sides to (re)weather proof it.

The FT101ZD is "THE" most popular rig for an 11 meter conversion that I know of. Yup, she's a hybrid. Along with all the superb advice given, I'd like to add watch the interboard connections. Sometimes a little re-dressing can cure a lot of problems.

568. how to make a 50::100 balun?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-29 00:18:15 UTC

Message-ID: <v3d1e0p8ll2uoob8ka5fr6r31vikhkhkgp@4ax.com>
Source record: 25200

I'm testing some 10/100 ethernet transformers and I need a 50:100 ohm balun for 30 - 80 MHz. How do I make one? (I need to measure return losses on the transformer. The spec is LT -18 db.)

Its not normally a problem, except for running your drill through
something important - go to your auto parts store and buy the
appropriate size grommet to fit the hole you are drilling, and at the
same time buy a blank grommet so you can fill the hole when you sell
the vehicle.

There is probably some legal reason why you shouldnt do this
(structural integrity of motor vehicle regulations) but, hey, does it
really matter?

You're probably right. I recently contacted Isotemp and Railtron and
got good results. I don't believe I have contacted Ovenaire.

OTOH, I have sometimes had better luck just calling vendors rather
than emailing. I think they find a phone call harder to ignore than an
email.

Never been an issue - with all the cars I have installed radio equipment
into I can't remember any that I couldn't get power and antenna cables
through an existing hole just by adding another 'hole' to the grommet.
There's usually plenty of space in existing holes for wiring, etc, to add a
few more cables - hardest part is getting the cables through the grommet but
a little common sense and this isn't a problem.

Although I'm sure that if all else failed your suggestion would be the next
best option - if you use a blank grommet as you suggest upon removal, I
doubt anyone would even know the hole wasn't meant to be there.

Cheers

Thanks for those firsts advices.
At the first time, we have found some bad solders, but probably
not all the ones.
We have remplaced the electrochimic capacitors in the main power
supply, they were very "tired".
When the problem arrives, the reception is cut on all bands but
sometimes, the frequency counter continue to display good numbers
only on some bands.
We're going to continue to climb this mountain, meter by meter.
Thanks.

Guillaume.

I assume you want to measure them on a 50 ohm test system. A bit mathy, but
you could use a minimum loss T pad and include the pad's loss in the math...

For a transformer, ther turns ratio would be square root two...

575. Bypass caps to Vcc?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-06-29 23:32:44 UTC
From: Bob Liesenfeld <wb0poq@visi.com>
Message-ID: <40E1FC1C.5A7E119C@visi.com>
Source record: 25207

Hi gang,
Looking over an old AM/FM radio kit I built some years ago, I notice that instead of bypass caps going to ground (negative side of 9V), they all tie into the Vcc line, which has a single bypass cap to ground with an associated decoupling resistor. Any thoughts on this?

Bob WB0POQ

576. Re: Bypass caps to Vcc?

Newsgroup: rec.radio.amateur.homebrew

Source record: 25208

The whole purpose of bypass caps is to return the RF currents to where they started from. Since it's typical to connect the negative supply to the chassis and use that as a 'common' point for V+ bypassing, many people think that bypasses should be connected to chassis 'ground'. In point of fact, you're really better off bypassing the V+ line (or V-, as the case might be) directly to the V- line (or V+, as the case might be). This is not a straightforward matter, and the choice of where's the best place to connect the bypass is often a complex issue involving the impedance of the return current path, as well as what other currents from lower level stages might be sharing that same current path. It's always good to prevent output stage currents from sharing the same return path as input stage currents. As was popularized in the movie Ghostbusters, it's not wise to "cross the streams".

Upon looking, I think the easiest thing to do is to buy a 50:100
balun. Something small with leads I can solder into a fixture. I found
one at TeleTech,model TT57E in a TO5 can.

Source record: 25211

Hi Goup de KJ4UO.

I picked up on for the Direct TV disk with the LNA. The LNA states a frequeny range of 19 to 23 cm.

I understand the the LNA gets it power from a DC voltage that is transmitted down the line.

My questions:

For the DC voltage on the cable, how much is required and how much is the max?

What is the IF down converter frequency?

Can I use my FRG-9600 which has continuous coverage from 60 to 934 MHz as an variable IF to decode voice data?

In general is there a good site to return to and get technical facts on DT equipment.

Thanks,

Paul

>For the DC voltage on the cable, how much is required and how much is the max?

The receiver typically puts either 13, or 18 volts onto the coax,
depending on whether it wishes to receive the lefthand or righthand
circular polarizations. There's often some voltage drop between the
receiver and the LNA/LNB.

>What is the IF down converter frequency?

There's no single downconverter frequency. The system uses a
low-noise block converter, which downconverts a whole range of
frequencies simultaneously. I believe you'll find the downconverted
signals located between 950 and 1450 MHz, if you aim the dish at a
DirecTV satellite. The block converter is designed so that its usual
outputs don't fall below 900 MHz - this allows a single coax to carry
both the downconverted satellite signals, and VHF/UHF television
signals via a diplexer.

>Can I use my FRG-9600 which has continuous coverage from 60 to 934 MHz as an
>variable IF to decode voice data?

I don't know whether the block converter will output frequencies that
low... they're below its normal output operating range.

For audio, maybe; for RF, no.

It's often not feasible at RF, especially at VHF & UHF. The lead lengths required to take all bypasses to a single point can introduce significant impedance which prevents the bypass from doing its job. In general, it's a good idea to keep 'circulating' RF currents local to the stage where they are generated so they don't co-mingle with other stages' currents.

You'll probably get better answers, but...

I once had an old MW radio that used tubes of this kind. It worked fine
with only 18V on the anodes. (two 9V batteries in series)

Don't forget that it will factor into your measured data. Can't figure out
what "LT -18 dB" is...Loss Tangent doesn't make sense...

If what you want to measure is a return loss of -18 dB, then the transformer
you buy better be better than that and you'll have to measure it into the
100 ohm load and do the math if is near -18.

Good summary, Joe. Return the current to the proper place is THE correct answer. Ghost Busters analogy is interesting...

...and don't forget circuit board layout issues. With a one (or two) sided board it may be expediant to use one or the other.

The IF (with a high gain) is usually the most susceptible to oscillation.

I would expect that the AM/FM is one of the "less" critical applications, acknowledging, however, that it is easy to get into trouble anywhere.

Doing an altavista search on "glowbug" will turn up at least one battery powered transmitter project, and lots of fun tube stuff.

Dave is correct about the IF freq, but: the local osc in the LNB
covers two ranges: 13 to 18 VDC it will osc in the low band, 22-28 it
will osc in the high band. The LNBs I've seen use an signal about
20khz sent from the satellite reciever to switch polarizations.
Adjacent channels are oppisitely polarized, circularly.

From: J M Noeding <la8ak@online.no>
Message-ID: <daq8e01clferh6vc0m13gprida6ssssu4d@4ax.com>
Source record: 25233

THE ALEXANDERSON TRANSMISSION IN 2004

Also this year there will be a transmission with the Alexanderson alternator on VLF 17,2 kHz, now on Sunday 4th July at:

08:30 UTC
10:30 UTC
12:30 UTC

The UNESCO Committee will have a meeting in Beijing, China in the last week of June, and will then decide whether Grimeton Radio will be included in The World Heritage List, or not. So the message sent on Sunday July 4th will include information about the result. We keep our fingers crossed!

The Radio Station will be open to visitors 10:00-16:00 Swedish time.

The number of visitors has increased noticeably during the last years, from 300 to 500 and last year to almost 800. The weather has been extremely good, so far.

We have had some problems with the keying of the transmitter last years and hope it will be better now. "Dots" has been missing quite often (not the operators fault!!).

The amateurs will operate a transmitter with the call "SA6Q" on 20 meter band during the day:

14.035 MHz CW

14.215 MHz SSB

QSL for both "SAQ" and "SA6Q" via:

E-mail: info@alexander.n.se

Fax: +46-340-674195

Mail: Alexander - Grimeton Veteranradios Vaenner, Radiostationen,
Grimeton 72,
SE-430 16 ROLFSTORP, SWEDEN

or via SM-bureau.

For further info see our web site: www.alexander.n.se

Regards

SM6NM/Lars

Hi John, 17.2khz audio is not audible to me because I am to old. 17.2khz RF or electromagnetic radiation is usually not audible to anyone, even dogs. I am sure if you were too close to a very strong 17.2khz EM field you could feel something or hear the effect the radiation had on close in objects, but I don't think you could hear the EM. Sound waves and EM waves are two different things.

612. BPL, the ARRL and the UPLC

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-02 11:26:02 UTC
From: John Walton <jdwalton@comcast.net>
Message-ID: <w9ednZYjgfnE2HjdRVn-jw@comcast.com>
Source record: 25245

ARRL's newsletter is a day early...they comment on Alliant Energy's withdrawal of their pilot project (seems that as expected the noise couldn't be notched out.)

at any rate, here's a link to the UPLC press release from June 22:
http://www.uplc.utc.org/?cbr_v=dcb&nt=true&cbr_eid=25276&p=admin&ct=contentbrowser

please note the swipe at the amateur radio community in paragraph 3

-- perhaps mary.patterson@utc.org , author of the press release, would like to hear from all of you who read QST, QEX and or AMQRP.

here's the relevant part of the missive from the ARRL:

==>UTILITY CUTS SHORT BPL TRIAL THAT WAS TARGET OF AMATEUR COMPLAINTS

Alliant Energy has called an early end to its broadband over power line (BPL) pilot project in Cedar Rapids, Iowa. The "evaluation system" went live March 30, and plans called for keeping it active until August or September. Alliant shut it down June 25. Ongoing, unresolved HF interference from the system to retired engineer Jim Spencer, W0SR, and other amateurs prompted the ARRL to file a complaint to the FCC on Spencer's behalf demanding it be shut down and the utility fined.

Alliant Energy's BPL Project Leader Dan Hinz says the ARRL complaint "certainly was a factor" in the utility's decision to pull the plug prematurely but "not the overriding factor." The main reason, he said, was that Alliant accomplished most of its objectives ahead of schedule. The primary purpose of the Cedar Rapids evaluation was to gain an understanding of BPL technology and what issues might be involved in a real-world deployment, Hinz explained. But, he added, regulatory uncertainty and other unspecified technical issues also factored into the choice to end the pilot early.

Hinz said Alliant is "moshing the data" to compile a written evaluation of the Cedar Rapids pilot, but the company has no plans at this point to move forward with BPL. Alliant did not partner with a broadband services provider, and it has no other BPL test systems in operation. The system used Amperion BPL equipment.

According to Spencer, five fixed Amateur Radio stations within proximity of the BPL evaluation system and two mobile stations formally reported BPL interference on HF. "The radio amateurs and Alliant Energy cooperated by sharing interference information," he said. "Alliant Energy turned the BPL evaluation system off twice to allow collection of extensive BPL frequency and signal level data--with and without BPL." He said Alliant and Amperion tried various "notching" schemes to rid amateur frequencies of the BPL

interference with only limited success.

The system included both overhead and underground BPL links to feed 2.4 GHz wireless "hot spots" for end user access. Hinz said the area's topography presented some challenges, especially with the wireless links. "I think in the end, we actually over-challenged ourselves with this specific pilot location," he said. And, despite "substantial progress" in mitigating interference, Alliant decided at this point that "it wasn't worth the extra effort" to resolve the thornier technical issues, Hinz added.

As for any broader implications, Hinz says he's always viewed BPL as a "strategic deployment technology," not one a company could roll out just anywhere and expect to be competitive with existing broadband services such as cable and DSL. "At least that's how we were looking at it," he said. "You have to find the right areas with the right topography with the right concentration of certain types of customers," he said.

"It's never been in my mind that BPL has to compete with the speeds of cable today," Hinz added. "It has to compete with the speeds of cable and the next best thing tomorrow as well, if it's going to be usable well into the future." He hinted that Alliant might want to take another look at BPL once the FCC has put BPL rules and regulations into place, and the technology has further evolved.

The ARRL's formal complaint to FCC Enforcement Bureau Chief David H. Solomon called on the Commission not only to close down Alliant's BPL field trial system but to fine the utility $10,000 for violating the Communications Act of 1934 and FCC Part 15 rules. Commenting on the termination of the Cedar Rapids BPL trial, ARRL CEO David Sumner, K1ZZ, pointed out that Alliant had tried for more than 12 weeks to fix the interference problem to a station 600 feet from its installation.

"In the end," Sumner said, "the interference was not eliminated except by shutting down the BPL system. Could the case against BPL deployment be any clearer?"

Spencer said he was happy with Alliant's decision, and he was gracious in expressing appreciation to the utility for working with him. "And thanks also to the ARRL and the Cedar Rapids BPL Steering Committee for their knowledge and efforts in making a truly professional evaluation," he added.

Still outstanding are some chronic power line noise problems Spencer has experienced.

For additional information, visit the "Broadband Over Power Line (BPL) and Amateur Radio" page on the ARRL Web site <http://www.arrl.org/bpl>. To support the League's efforts in this area, visit the ARRL's secure BPL Web site <https://www.arrl.org/forms/development/donations/bpl/>.

==>UPLC COMMENT SHOWS BPL CAMPAIGN STARTING TO PAY OFF, HAYNIE SAYS

ARRL President Jim Haynie, W5JBP, says a remark the United Power Line Council (UPLC) made recently about Amateur Radio shows that the League's BPL message is getting through. In its reply comments on the FCC's BPL Notice of Proposed Rule Making in ET Docket 04-37, the UPLC's Brett Kilbourne claimed that members of the BPL industry are the real experts on the technology, "not a misinformed set of armchair amateurs that still use vacuum tube transmitters." A subsequent UPLC press release repeated the swipe, drawing a storm of protest from the amateur community. Haynie said this week that he took comfort rather than offense at the intended affront.

"I thought that the comment was a good indicator that the work that the League has been doing on multiple fronts is beginning to pay off," Haynie said. The League's FCC filings, technical studies and information on BPL, he said, have made it "very embarrassing" for the BPL industry to keep insisting "that the emperor is wearing clothes," so it's resorted to name calling instead.

Haynie said he remains puzzled that the BPL industry appears unwilling to support its claims that "the risk of interference from BPL is extraordinarily low, because it produces only minimal radio frequency energy at a few points in the system," as the UPLC's press release asserts. Any harmful interference that does occur, the UPLC claims, can be "mitigated" using a variety of techniques, "including frequency notching or frequency shifting."

"Just saying 'We said it's not going to interfere' is not going to cut it," he said. Haynie challenged the BPL industry to sponsor independent, professional engineering evaluations of the technology's interference risk. "Let's see what they've got."

Haynie said that while he found the UPLC's "armchair amateurs" remark amusing, its severe criticism of the National Telecommunications and Information Administration (NTIA) Phase 1 BPL report and comments in the proceeding raised his eyebrows a bit. In its press release, the UPLC said "NTIA's recommendations and ARRL's naysaying are misguided" and that the UPLC has "forcefully replied" to interference concerns.

"For Mr Kilbourne to come out and say they [NTIA] don't know what they're talking about, he might as well shoot himself in the foot," Haynie said, pointing out that the White House, which is promoting BPL, is putting a lot weight on the NTIA's recommendations.

In its comments, the UPLC said the NTIA's approach was "fundamentally at odds with the Part 15 rules" and "unjustified" by BPL's interference potential.

In response to the criticism leveled from the amateur community, the UPLC declared its "support for Amateur Radio remains unabated," but expressed concern for "uninformed armchair quarterbacking by a small number of amateurs." The UPLC also said it has "sought to work with ARRL," citing its offer to help resolve "a complaint in Cedar Rapids, Iowa." Alliant Energy prematurely shut down its BPL pilot system in Cedar Rapids June 25.

Interference complaints from amateurs were a factor in the utility's decision.

==========
Don't know how large this rx is ,but generally 'lunch box variety ' type of (usually transparent) plastic enclosures with a good seal ,available in most DIY stores ,are weather proof. Suggest you have a look at B&Q , Home Base , Focus , Wickes ,etc.
However in order for these enclosures not to suffer from the sun's UV radiation causing the plastic to become brittle ,it is important to paint the outside ,incl the lid , Black (Hammerite Spray will do fine) ,not leaving any exposed area of plastic unpainted.
Recently I replaced such a box ,which had been accommodating an outdoor LF antenna amplifier ,after more than 9 years of good service .

I'm with you Gary- still watching Superman on TVLand, and now getting to
read Carl & Jerry again- great stuff.

Radio Constructor, a UK publication that folded some years ago, used to have
a column entitled "In Your Workshop", IIRC, featuring the adventures of
Smithy, a TV/radio repairman and his assistant, Dick Their exploits weren't
as exciting as Carl and Jerry's, but quite amusing.

Just goes to show ... I had searched RS and others before based on 'project box'. Searching again under 'enclosure' did the trick. RS have more styles and sizes than you could shake a stick at ... so problem solved. Thanks for the responses.

It appears that your provider doesn't carry that group. A lot of
providers don't carry binaries groups because they tend to be _big_,
have high traffic levels, and get used to move porn of various sorts.

You _could_ write a letter or send E-mail to the appropriate folks at
your provider, asking them to carry the group -- and that might work.

You could pay to subscribe to, say, supernews, or to another news
provider that carries the groups you want.

Have a quantity of Radio Communications Service Manuals, both Commercial & Amateur that I have rescued from the Dumpster. If you are a Johnson 2 way dealer, I have a large amount of surplus manuals, RF Transistors, SMT components, covers, parts in general that came from the PPL-6050, 577 generation of Johnson Equipment. I have itemized some parts, but am considering selling them ALL as a LOT purchase especially the smaller (don't know what they are) parts...CHEAP!

Please check my site: www.rodemi.com for what is available. I am updating the site as time allows.

If you are interested in buying the Jsn parts as a LOT purchase at a very reasonable Price, let me know and we can work it out. Contact me if you have any interest
I'm quite negotiable..have to make room in the garage for my vehicles!
Thanks for looking....Norm VE3CZI

WHY? All you need to do is remove the "NO SPAM". AND if you had read my reply to him in group when my message bounced, I even stated that. So, unless someone has trouble reading, then they wouldn't have that problem!

But ya know.... right now, I don't really give a rats ass. I've had enough of this crap. My message bounced, I replied in group. I've yet to hear from him, SOooooo......

Hi,
fixed similar case some years ago, the reason was that one contact inside
VFO assembly had never seen solder. It was wrapped but not soldered, all
other contacts were OK.

After the fix everything worked fine. I do not have the serial number, it
was a friend's rig that has since been sold.

73!

650. EMI problem...

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-05 20:31:27 UTC
From: nospam@nowhere.nil
Message-ID: <qjdje0tqv20u2q62omijgfva4o2nrc62r9@4ax.com>
Source record: 25132

I'm trying to track down an EMI problem.
This is with my solar powered RC plane.

Specifics:
I'm using standard 6M RC gear from JR on ch 04, FM on 50.880 Mhz.
I've got two receivers that exhibit exactly the same problem.
A JR FM receiver and a berg FM receiver.

Both work fine until I turn on my switching solar maximum power point tracker.

The power tracker runs 6 seperate channels at about 25W each channel.
The switcher runs at ~ 150Khz +/- 20Khz

I've filered, shielded and added caps with very little effect.

The receiver is in the tail of the airplane the converter in the front,. There is currently no electrical connection from the receiver to the other electronics on the plane. I'm currently powering the receiver from battries. The only connection is capactive to the carbon fiber airframe.

I'm using an Icom R3 to hunt for the EMI.

The Icom receivers shows the 50.880 signal clear as a bell.
When I turn the TX off the icom sees no no difference in background signal with the power converter either on or off.

When I run the Icom receiver tuned to 50.880 near the RC receiver I see a significant reduction in range, but not as much reduction as when I run the power converter.

My first theory is that I am generating IF or image noise that is clobbering the receiver.
To test this I set a signal generator out next to the receiver and ran it at 450Khz, 455Khz and 10.7 Mhz with no effect on range.
(signal generator is an old digital fluke runing 13dbm into a 2 ft peice of wire)

Any ideas on what I can do to solve this... it is driving me crazy, I've been working on it for more than a month.

Paul (Kl7JG)

Try the image frequencies (probably 29.48MHz, but possibly 72.28MHz).
You may also want to try RX +/- 455kHz as well.

This may be simple overload of the front end of the RC reciever. I suspect it has little selectivity before the first stage and the tracker unit is simply blowing through the filter.

It's been quite awhile since I did any RC work, but if it has a separate Rx Antenna input to the RC reciever, you might try wrapping the reciever i tin foil, and adding some high pass filters between the antenna and the reciever. Make sure to shield the filters too, that much energy could easily couple into the coils used in building the high pass filter.

How would one of the Minicircuit Prepackaged can filters be?
My guess is smaller, lighter and more robust than what I can build.

I've been using some adhesive backed Cu and Al tape to shield things,
tried shielding the Rx, to no avail, but a front end bandpass filter
was going to be my next step.

Paul

John,
Are you saying you have some SRDs available?
I could use a couple in a GPR I'm working on.
Part of the Sample pulse generator.
Don

Hello everybody,
I just finished my first homebrew radio, a VHF receiver with PLL, and it's time to put it in a box ! I've often read that HF circuits should be put in metal boxes, but I don't know which one should choose. Are "sealed" enclosures such as this one
http://www.velleman.be/common/product.Aspx?lan=1&id=7318
better than boxes like that one
http://www.velleman.be/common/product.Aspx?lan=1&id=11184 ?

And do you think that plastic and ABS boxes are really bad for HF circuits ?

Thanks for your answers !

Hi,

I've tried Googling but without success. Anyone got a 'sheet lying
around in .pdf or whatever they could post to abse?

Thanks.

Hmmmm. I get a "404" at both URL's.

In 22 years of this hobby, RF and audio, I have used every material you can shake a stick at, even gold.

Plastic, IMO, is for Saran wrap and should stay there ;-)

Wood, tin, copper, brass, aluminum and steel, in that order, are my personal preferences.

For HF circuits, tin is a superb shield, soft enough to cut with scissors and easily solderable. As long as your HF circuits are well shielded, the outer cabinet is restricted only to the materials that will be needed to withstand the abuse you want to put it through.

Duncan you didn't check your own site (I assume you're the Duncan of
Duncan Amps) - it has no data for this tube. The NJ7P has data but no
base diagram, but Frank's has the page from RCA:
http://frank.pocnet.net/sheets/049/7/7213.pdf.

Good site, none the less.

Enclosures can cost you more than the whole rest of your project if
you're not careful.

The ideal box would be an aluminum or copper box, seamless, with no
holes. This would present problems with controlling your device,
getting power into it and signal out, so you have to make some compromises.

Depending on how sensitive your circuit is and how much RF it generates
you can go everywhere from no enclosure at all to a machined metal box.
For a VHF rig you probably want fairly good shielding.

For enclosures I go to hamfests and garage sales and buy old CB radios.
After I rip the guts out this gives me a good looking enclosure that's
designed for RF and costs way less than what a new one would.

Alternately you can make a really good, ugly enclosure by soldering
sections of unetched circuit board together -- see if there's a surplus
shop in your area that sells the stuff. I mount lids by soldering
sections of 1/8" brass tubing to the inside walls of my enclosure; you
can tap these to 4-40 and run a screw in them. Once you're done making
it work you can put it in a plastic box.

Hi Tim, I did check before posting - there are links to four data sources
from the TDSL page linked above:

Vade Mecum page on my own site with basing, data, curves
NJ7P with data (but no pinout/curves)
A link to the RCA data sheet on Franks site
A 2nd RCA sheet with lots of mechanical data, again on Franks site

Let me come up on the other side here. My list would be

plastic, aluminum, wood, copper, brass, tin, steel

OK, I'm lazy. If the circuits are well thought out they rarely need shielding, and plastic is easy to work, doesn't tarnish, looks decent, and it's cheap.

Copper tarnishes, steel rusts, and brass and tin are darned near impossible to get. Wood is a bit of a pain because to get decent strength it needs to be too thick for many controls. Besides, I'm a terrible carpenter!

The main problem with plastic is that cases of the size you need, whatever that size is, seem to be hard to find. But with a decent brake, you can get a sheet of aluminum and make whatever you want. Of course, it's a bunch more work than just buying a plastic case. But, you get exactly what you want. I don't think I would actually go out and buy a metal case unless it was something I considered very important. Getting a case of just the right size is just as hard as plastic, getting one that looks good even harder, and it's going to be bloody expensive.

One thing that works well sometimes ... cigar boxes. They are cheap, decent looking, especially with a little finishing, and come in a wide range of sizes. The problem is that you need to be careful with circuits that involve small controls, because of the thickness of the wood. There are plenty of cigar shops around that sell these things for a decent price.

So mostly I stick with plastic, and use aluminum when I get the urge to bend some metal.

I'm bad -- I did see the other links at the bottom but I missed the PDF.
Since I didn't see the pinouts data up on top I assumed (with the full
meaning when you break it into it's three syllables).

My original complement on your site still stands, however.

I have a bunch of small feedthru caps that I need to measure their Zo to assure it's 50 +/-10 ohms. Any thoughts on how to do it? I'm going to try to put a 50 ohm load on them and look at them with a network analyzer. I should be able to get it's Zo from the VSWR, no? Any other ways?

Hmmmmm....Are you sure you mean feedthrough capacitors? My
understanding of FT caps is that they are a very low Z from the
terminal(s) to ground while allowing a DC voltage to pass through. I
don't see where you are getting the 50 Ohm Z value. But, perhaps I have
missed something. More info?

Not much more info. These are definetly feedthru caps and they want
them verified to be Zo of 50 +/- 10. (We're a small parts testing
house) Maybe they're meant to be signal feedthrus? I assumed they were
for power lines ,but you're right; being Zo = 50 they must be for
signals?

Feedthrough caps are designed to be low inductance caps to ground- typically used to ensure no RF gets through on DC or bias lines. Never heard of a 50 Ohm designed feedthrough. My junkbox is full of 0.001 and 0.01 feed throughs. To be 50 Ohms it would need to be coaxial in nature- they may exist but never saw one. Bulkhead barrel connectors would fulfill that requirement.

I assume you do testing for profit, this is an Amateur Radio newsgroup. But, since you asked :-).

>These are definetly feedthru caps and they want
>them verified to be Zo of 50 +/- 10.

The Zc of a capacitor (capacitive reactance) is frequency dependent. Not sure what Zo of a cap. refers to. At some frequency the capacitor will have a Zc=1/2*pi *f*c. I am sure you know that. An ideal capacitor will have a Zc=0-jZc. A real world capacitor will have a non-zero real part of R+-jX. To have the real part 50 ohms(Zo), must mean the frequency is in the VHF region or higher. To measure what you want, you need a Z meter with the capability of measuring the complex impedance of the feed-thru capacitors at the frequency of interest. I have an antenna analyzer that I use for that sort of thing, but it only reads capacitive reactance at the frequency of interest.
Not sure if this helps?

Thanks for all the responses. There's not much info here. The lab manager gave me about 10 feedthru caps to verify the impedance. The "official" looking tag in the bag says "Zo=50+/-10 ohms". That's it. No freq, no capacitance. For sure they're feedthru caps, built like you're typical feedthru cap. I figured, for testing purposes, treat it like a small section of coax.I'm not even sure what freq they want it checked at. I'll have to get more details.

Curious. Very curious. From my experience, measuring the 'Zo of a feedthrough cap' would be something like measuring the 'color' of a miles/gallon rating of an automobile. Not an applicable unit of measurement.

> The
> "official" looking tag in the bag says "Zo=50+/-10 ohms".

And no manufacturer or part number on said official looking tag?

If it were April, and you were a new employee, I might suspect a bit of chicanery here. ;) ;)

Keep us posted. I'm always willing to learn new stuff. :)

Sounds to me like they are just feedthrus, not feedthru caps.

I don't think there's any way that a feedthru cap could have a Zo of
50 Ohms (pure resistive.) They are simply not made to pass RF; their
purpose is to serve as a short to RF.

Hi,
I am looking for the article 'Handiman's Guide to MOSFET "Switched Mode"
Amplifiers: Part 2' by NA5N that appeared in the Spring 2003 edition of
QRPp magazine.

To my understanding the magazine does not exist anymore, and even
NorCal's QRP website is gone. (I know they merged with NJQRP into AmQRP.)

Does anybody know a way to order a past issue of QRPp Magazine?

Thanks,
Paolo IK1ZYW

681. '73 Magazine'?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-07 14:56:43 UTC
From: Terry <tsanford@nf.sympatico.ca>
Message-ID: <qcUGc.28082$WM5.1204123@news20.bellglobal.com>
Source record: 25063

Is the 73 magazine still published?
If not when did it cease?
Seems to be a most interesting magazine for amateur constructors.
For example I have a November 1966 issue that; "Is published by 73 Inc.
Peterborough New Hampshire. 03458 ..... "
Publisher Wayne Green W2NSD, Editor Paul Franson WA1CCH.
Many thanks for any info or comments.
Terry.

No, the magazine died last fall (or was it the fall before?).

Of course, it had changed quite a bit since 1966.

684. Wide Freq Range?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-07 16:11:21 UTC
From: Rude Dog <snjr.spam@charter.net>
Message-ID: <10eo89b6kp7sd44@corp.supernews.com>
Source record: 25066

I hope members of this group can help me. I am in the Army National Guard and I am charged with setting up emergency communications for my unit. I need a transceiver that has a wide frequency range that can be issued to our civilian emergency responders for commo with our land mobile units (we cannot issue our military radios). I am looking for approximately 60 MHZ thru 500 MHZ.

Any suggestions?

Thanks!

685. Re: how to meas Zo of FT caps?

Newsgroup: rec.radio.amateur.homebrew

Source record: 25067

To determine whether you really have a feedthrough capacitor, use a simple capacitance meter to measure the shunt C. (Surely an electronic parts measuring company has the capability to measure capacitance.) A feedthrough capacitor will probably measure somewhere between 100 pF to 0.1 uF, and the Z0 specification is meaningless, as others have pointed out. But if it's a coaxial transmission line feedthrough, the shunt C will be a pF or so at most.

To measure the Z0 of a coaxial transmission line feedthrough, you'll probably need a high speed TDR, like the Tek TDS 820, 11801, or older gear with high speed TDR plugins. HP makes similar gear. The problem with using a network analyzer is that the line is probably too short to make a good measurement, unless you have a 40 GHz or higher frequency analyzer, a really good termination, and know how to interpret the results. The advantage of a TDR is that it graphically gives you the Z0 as a function of physical position, so you can see the Z0 of the feedthrough itself, independent of the connecting cable and the termination. However, to get the necessary resolution so you can see the Z0 of a physically short line like the feedthrough, you need a high speed TDR. That's exactly the sort of job that high speed TDRs are designed to do. There's also a cost issue. The last time I checked -- some time ago, admittedly -- a new good high speed TDR was about $25k, and a good 50 GHz network analyzer was roughly $500k. This price ratio would be about the same for rental units, also.

See this article:
<http://www.stealthpegasus.com/modules.php?name=News&file=article&sid=125>

Some libraries may have it.

Ham fests may occasionally have stacks of old magazines as well.

The publisher used to sell CDs of back issues. Not sure where to find
them now.

Many thanks to all who replied.
I found the article describing the decision to cease publishing; but
searching could not found a source for any CDs.
CDs would presumably be a very compact way to store 73 literature. Any URLS?
Thanks again. Terry.

No. 10 pFd at 1 GHz has a reactance of 15.9 Ohms. That tosses
the VSWR in the bucket if that is part of a "line section."

A "small capacitor" of 100 pFd at 100 MHz has the same reactance
of 15.9 Ohms.

Feed-throughs were designed to be SHORTS on purpose...

Well here's what I did: I treated it like a peice of coax. I made a fixture to hold the "feedthru" with semi-rigid coax on one side and a 50 ohm chip resistor on the other. I dropped in a short peice of coax and cal'ed to that. Then checked VSWR, was about 1.00something. Then I took out the coax, dropped in a few feedthrus and got VSWRs about 1.04 - 1.06, which works out to about 53 - 55 ohms or so.
How's that sound?

Besides the obvious equipment limitation, there may be laws limiting what
you want to do. The Guard *might* escape prosecution, but your volunteers
might not.

I wonder if there might be military surplus gear available that fits?

You must follow FCC rules and regs.
Depends on what your land mobile units modulation is, AM, FM, SSB, SS, FHSS
?
You can get narrowband FM radios cheap in some parts of the bands you
indicated and use "talk around"
Or just get cellphones.

Hi gang,
I just boxed up an RF voltmeter per LA7MI. Works well. I suppose it could be replaced with the simpler RF probe and digital voltmeter, but its nice having a dedicated unit.
BTW, I could not find a CA3140 IC so I used a National LMC 6081 single supply opamp in its place. Bonus: No offset pot needed for zeroing.
:) I can't find the URL right now, but if anyone wants the skez, I can post it as a gif file.

Yup, thats it except the version I built uses a higher Z probe, so as to be able to poke around in a ckt without loading it down too much, rather than the terminated version on this page.

"Ignoring?" No. Spare me a lecture. 10 puffs IS a "small
capacitor. You were not talking "inductance." 10 pFd IS a
15.9 Ohm reactance at 1 GHz. That's also a small reactive
shunt on this mythical "line section."

>I grant you, a typical feedthrough capacitor is designed with large
>capacitance and is used for filtering, but that does not preclude one
>from being designed to "look" like a piece of coax if the designer
>wishes. And that was the original question.

Sorry, no. The original question concerned testing of what
LOOKED LIKE "feedthrough capacitors." The tester was thinking
of "treating it like a small section of transmission line."

Based on the response of actual testings, such as very low
VSWR measured, the gadgets are probably just wire feed-
throughs intended for something like passing through a
hermetic seal. Those would have very little capacitance and
thus would have very little discontinuity...the VSWR would not
be raised very much.

If those "feedtrhoughs" had really been capacitors, then, in all
probability, they would have tested as capacitances on a bridge
such as a 1 MHz bridge. A handheld C or L/C meter could have
read that on a 1 nFd or 10 nFd scale.

Without further ado, based on what was written by the person
who has the devices, my opinion is that they are just wire feed-
throughs with minimum capacitance and the inductance of a very
short piece of straight wire. Those MIGHT work as "line sections"
going through a hermetic seal wall of something...but not a very
practical way to run a transmission line through that wall.

Feed-through CAPACITORS were NEVER rated by "characteristic impedance" (Zo). Not in 1964, not in 2004, not in years between.

Wire feedthroughs for sealing-type bulkheads are seldom rated for anything but current carrying capacity and withstanding or flash-over voltage. Those have just conductors going through with minimal capacity to "ground" and minimal inductance straight through.

Me again gang,
I've been torturing myself this evening by drawing wee little lines on scraps of blank pc board material to make 'headers' for some surface mount ICs. In the past I've had the usual troubles with the resist (black Sharpie) being etched away before the rest of the board was done. I suppose most of us know that warmed etchant works faster than room temperature juice.
In the past I have warmed my ferric chloride in the microwave. Well tonight I got a bit carried away. ;) I put about 4oz of juice in a plastic cup and nuked it for a full minute. Holy smokes! That stuff was *steaming*! So....."plop" goes my little homebrew surfboard into the brew. That puppy was fully etched in less than a minute!
The microwave seems to still make popcorn and I am not in a coma (yet), so I guess I will call it a success. BTW, the Sharpie ink survived nicely.

Hi Group,

I have a Icom 706 and dipole up for the 6 meter band. In scanning the band just before 50MHz I hear a few baby monitors.

Assuming that I am running 100 watts and the dipole on SSB, will the parents hear my signal or do baby monitor manufacturers know that hams are just above this band and put filtering on the input?

If so, I guess that I could switch modes to FM and talk to them. I see a simple modifications for the rig to allow out of band transmission but I am a bit lazy to open the rig up and do it. I would like to get on the new 60meter band which the 706 gxII does not have as open transmit.

I've worked with at least ten "engineers" and dozens of bosses who,
given a similar bag of feedthroughs containing a slip of paper saying
"RPM = 2400 +- 1%", would work for a week designing a test to verify or
disprove the spec.

Making growling sounds at 2:00AM on 49.830,49.845,49.860.49.875 and 49.890
Is a total riot! The sound of a wild boar, a rabid dog will do just fine.
Play it for about 10 seconds, then unkey and wait for the circus on the
other end.

I just put the plastic container with the etchant and PCB in a larger container partly filled with boiling water. Etching usually takes about 5 minutes, with continuous agitation.

Long before the days of Health & Safety In The Workplace,
I worked in the research dept attached to a power station
and we used to boil the FC solution in a saucepan on the
little mains cooker that we had.

Insofar as the saucepan was aluminium (aluminum to the
non-English-speaking Yanks), I am surprise that there was
any "strength" left in the solution to etch the copper!

(Having made the mistake of using an aluminium stirrer in
my own etchings!)

I find that faster etching = cleaner etching, too, with less risk of
the pen marks getting washed away and exposing areas you *don't* want
etched. Maybe there's a point where this rule breaks down, but I
haven't come across it yet and I use a microwave, too. I'm sure my
wife wouldn't approve, but since I don't have one, I can do as I damn
well please! :->

Have you contacted ARRL? It was probably designed by a staffer. I
prefer it when they credit the designs or reference the original article.

I have the '64 handbook and have eyed that design myself.

The wisdom of the Iraq war will only be revealed by history (and maybe
not even then), but the bulk of the troops are risking their lives for
their country and the Iraqis and are therefore, ipso facto, heroes.

Our fearless president, who "served" in a time of war but never saw real
combat, who got to be a jet jockey in the national guard at a time when
any 22-year-old with another daddy would be flying jets over Vietnam,
who is happily risking the lives of other's sons and daughters while his
children and nieces and nephews, and those of his advisers, all stay
home safe and sound, and who ignored the advise of the one man in his
cabinet with actual military experience, is another matter.

The wisdom, or, rather, the complete lack of it, is apparent now.
Saddam Hussein has done some wicked things, almost as wicked as
Ronnie Reagan in Nicaragua, but Hussein was a paper tiger at the
end, controlled by UN Sanctions. There was no point to the war, and
just like the attack on the World Trade Centre by Al Q'Aeda, was
initiated by religious loonies, Blair, Windsor and Bush. Many people have
died needlessly to suit the political ambitions of this Terrible Trio.

The troops are not fighting for their own country - they are illegal
invaders
no different to the behaviour of the Germans and Japanese in the 1940's.
Nobody who goes around the World with the specific intention of attacking
and killing his fellow man is a hero - something left behind on the
pavement by a passing dog, yes, but a hero? No way!

The troops are fighting for the Iraquis? With the number of attacks on
them today? Bwahahahahahahahahahahahaaaaa!

Source record: 25008

Hello everybody,
I have build a VHF receiver for the airband, published in the magazine Elektor a few years ago, and I've managed to build a PLL to improve it. The PLL is build on another PCB, that is connected to the main circuit, and that replaces the original potmeter, in order to choose the frequency. The PLL is able to lock on the right frequency, but the receiver is a lot more noisy, and it seems really less sensitive with the PLL. See these sketches, I think it is better than a long explaination.

http://www.mcarsweb.com/_divers/1sketch.jpg
http://www.mcarsweb.com/_divers/2sketch.jpg
http://www.mcarsweb.com/_divers/3sketch.jpg

I have also included the schematics of the VCO (with the buffering transistor, T4), and the basic schematic of the PLL (taken from a Motorola application note). I don't know where the problem could come from. I would say from the bad buffering of the VCO output, but I don't see how it could be improved.

http://www.mcarsweb.com/_divers/4VCO.jpg
http://www.mcarsweb.com/_divers/5PLL.jpg

I'm really getting mad with this problem ! So thanks to all of you who will answer ;-)

Thank you, Jane Fonda. Will you be spitting on your own people when
they come home? You could look at some old films of ordinary soldiers
coming home from Vietnam and their reception from anti-war protesters
for guidance on how to do it.

Don't pay any attention to the interviews with the anti-war protesters
20 years later, when they were expressing guilt and deep regret at their
actions -- that might erode you supreme self confidence, and make you
see yourself for being as mindlessly extremist as the whole Bush crew.

There's got to be a special place in hell for fundamentalists of all
stripes...

736. Announcing 'hifi-am', to discuss High Fidelity AM tuners and hobbyist transmitters

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-08 18:49:29 UTC
From: Jon Noring <jon@noring.name>
Message-ID: <bq5re0p3nog28n89vtnp4lc04eimlp14op@4ax.com>
Source record: 25018
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur,rec.radio

Hello,

I've created a discussion group (mailing list) to discuss high fidelity AM tuners and hobbyist transmitters. Appended below is the more detailed group description.

To subscribe to this group, either go to the group home page (at Yahoo) and subscribe there (you will need a YahooID):

http://groups.yahoo.com/group/hifi-am/

Or, if you don't have a YahooID, send a blank email to:

hifi-am-subscribe@yahoogroups.com

Looking forward to seeing you there!

Jon Noring

****

Group Description for hifi-am:
==========

The purpose of hifi-am is to explore the possibilities of high fidelity AM tuners and hobbyist transmitters for medium-wave (or better known as the broadcast band, appr. 520 to 1720 khz.)

Although most commercial AM broadcasts are definitely not high fidelity (due to various factors including, in many countries, audio bandwidth restrictions), there are nevertheless a few commercial stations which broadcast with audio quality approaching high fidelity. For example, in Australia, because the number of stations is fewer and the country quite large, many stations broadcast with quite wide audio bandwidth, approaching 15 khz.

There is steady growth in interest (in the U.S.) for non-licensed hobbyist broadcasting in the BCB (per FCC "Part 15"), which is restricted to 100 milliwatts and a three meter antenna (among a few other minor restrictions). With a high efficiency antenna, it is possible for such neighborhood broadcasting to be heard about 1/2 to 1 mile from the transmitter. There are quite a few progressive and alternative stations broadcasting this way. For a wonderful example, see Radio KMTZ.

More importantly, it appears there is no specific restriction on audio bandwidth for Part 15 transmissions. Thus, if this is true, the broadcasts can approach high fidelity (15 to 20 khz audio bandwidth.)

Although discussion can focus on the general topic, it is hoped this group will catalyze the development of hobbyist kits for high fidelity AM tuners (digital, solid state, and tube) and for high fidelity low-power (Part 15) AM transmitters. It should be fun to consider the many possibilities.

Just to make sure that I'm universally reviled, I must point out that
he's a jerk, not a threat. People who want to abandon our hard-won
freedoms in exchange for the illusory "security" that comes from
right-wing totalitarianism are threats as well as jerks (see John
Ashcroft and Donald Rumsfeld for examples).

740. Strange Redifon highlevel mixer (+20dBm)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-08 19:17:57 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <427re0p9vnfe123ccu2g2351lrgds7rg7o@4ax.com>
Source record: 25022

LA7MI Stein Torp writes that he has tested a mixer which was used in a Redifon mobile transceiver in the late 60's, but using modern components. The input transformer is a pentofilar wound type with 5x 3turns (0.25mm enam cu wire), see drawing for the type of two hole core used in the transformers.T2 and T3 are wound with 2x 3turns 0.3mm wire. With input on 80m and 10.7MHz IF (LO = 14.5MHz) 3rd order IP on the input was measured to +20dB, and the strange is that output termination is not critical at all. It is possible to terminate it with an xtal filter and still obtain +20dBm, which is not at all possible with a ringmodulator. Measured the 1dB compression point to +10dBm, see http://www.noding.com/la8ak/12345/n16.htm

They're 50 ohm RF and DC feedthrus. Here's the company:
http://www.shp-seals.com/products_and_Services.htm
Click on bulletin 100. Most50 ohm types gave a VSWR of 1.05ish, giving
about 53 (or 47) ohms. I also had a few of the DC type that gave a
VSWR of 1.4ish, leading to about 25 ohms (or 75 ohms, could I check
the phase to see which?).

Gentlemen:

I did not mean to be the catalyst for a heated debate. My goal was simply to obtain information about a radio that will be utilized by responders during an emergency to contact my unit for assistance in manpower, vehicles, and aircraft.

For the most part, soldiers are apolitical. Therefore, I do not have an opinion on whether or not the war in Iraq is politically prudent. However, I will tell you as an Infantry Officer that the invasions of Afghanistan and Iraq were tactically prudent. The objective of warfare is to seek out, close on, and destroy an enemy. It is as simple as that. It is the "politicking" that muddies up that objective.

Strategically, the United States has sought an enemy (terrorists) and has closed on that enemy by selecting the battlefields of its choice. The numbers of terrorists who are migrating to those battlefields are in the thousands. Coalition forces are destroying those terrorists and reducing their ability to wage war as we speak and will continue to do so in the near future. The result is the terrorists are engaged in the Middle East, not in America or Europe.

The enemy successfully attacked Spain and killed many civilians. The enemy attacked to change the outcome of an election and Spain succumbed to the efforts of that enemy. People claim the reason Spain was attacked was because they had forces in the Middle East, however, Spain has been attacked by terrorists before the Iraq war (e.g. Barcelona 1987). It is likely Spain and all of Europe for that matter will be attacked again, primarily because of their relatively close proximity to the battlefield, until we defeat terrorism.

Regardless of your political position one point is clear. We must win this war on terrorism.

Tim:

I did get some email responses with recommendations for civilian transceivers with relatively wide freq ranges. I guess I was hoping the homebrew gang could come up with the "silver bullet", you know something like...

"oh that's easy, you get this x-brand $199 mobile and change a few jumper settings and presto a transceiver with every frequency you ever wanted!" :-)

Thanks!

Rude

The problem is that what he had asked for, continuous tx coverage for
"approximately 60 MHZ thru 500 MHZ", would be technically difficult,
and thoroughly illegal for amateurs.

That would cover from (almost) the 6 meter band, through all of VHF
and all of UHF, including a variety of licensed services, public
service, business bands, marine bands, , aircraft bands, amateur
bands, restricted military bands, etc.

Not sure whether FM is sufficient for what he wants either, or if he
needs multiple modes, making for more complexity and $$.

No company is going to make a radio which is illegal to own or use for
most of the country.

There are a few handheld models, such as the Yaesu VX-7, which are
capable of RX on most of the bands and modes he wants, and TX on 3 or
4 amateur bands (plus the MARS/CAP frequencies next to them).

Looking at getting his people licensed as amateur operators, then
MARS/CAP certified to mod their radios, might meet most of his
requirements.

He would still need to check legalities with the FCC on using amateur
bands for this purpose. Not clear to me either way.

Happy trails,
Gary (net.yogi.bear)

>"approximately 60 MHZ thru 500 MHZ", would be technically difficult,

One reason that we have broad band power amplifiers for the 1-30 MHz range is that we have transistors with sufficient (> 10) _current_ gains at the highest operating frequency (i.e. the transistor fT is at least 300 MHz).

To reach 500 MHz operating frequency, the fT would have to be somewhere close to 5 GHz, which is available at low power levels (< 1 W), but not with significant power levels.

It should be noted that even if there is no _current_ gain above the fT frequency, there might still be some _voltage_ gain (and hence _power_ gain) above transistor fT, especially when tuned loads are used. This is why you can build VHF/UHF amplifiers for a limited frequency range with considerable power output.

Please check your rule book.

There's nothing wrong with an amateur _owning_ a piece of equipment capable of transmitting on all those frequencies, it's just not OK for us to actually do it.

I read a QST article recently (I think in the July issue). Civilians must be amateur radio operators to use the MARS frequencies, but military operators need only the approval of their CO.

But you're right in that there isn't a continuous coverage transceiver. There are both base and handheld units that will cover the various bands (probably with separate final amps in the transmitters).

If this is for MARS/CAP operation you should see if there's an active
MARS group close to base. There has to be a few amateur operators in
your unit who may know someone, if not you could contact the ARRL
directly and see if they could help.

|Is two port theory even being taught in engineering schools these days?

Beats me Tom. I'm retired, I know nuttin' 'bout engineering school.

I do know that if someone had brought me these devices to test, the
first thing I would have done would be to try and talk them out of
doing it.

I did that often. I used to see things like big LC power filters with
a solder lug on one side and two feet of shield wire coming out of the
other side with a pigtail on the far end and an attenuation spec that
went from 10 Hz to 10 GHz.

Damn fool engineers would think, well I've got an AMRAAM missile with
a 10 GHz transmitter, so I better have a filter that rejects 10 GHz.
Trying to explain that the device can't be measured to the design
engineer and the spec writer was almost a pointless exercise.

I can say that after my first retirement and subsequent rehire to
manage a components engineering group that was doing the spec writing,
we didn't do that crap anymore.

Specing and measuring feedthru filters was one of the most pointless things we ever did. The specs all measure attenuation in a 50 ohm system and the filters are never used in a 50 ohm system. In fact, nobody ever knows what the source and load Z are at the test frequencies so they don't know what they need or what they get.

Oh well, it was a pretty good living. Thank you taxpayers.

Hello,

The only one I know of is DTMFF and you can find it at...
http://www.bookcase.com/library/software/msdos.rec.hamradio.html
It is old (1997) and runs under DOS.
It's cardware.

Maybe someone else will know of one a little newer.

Wes makes a valid point about the source and load impedances being unknown in practical applications. The filter performance is going to be different from the performance measured in a 50-ohm system.

But that doesn't make a 50-ohm measurement completely "pointless". In order to select a filter, you have to make *some* attempt to characterize the performance of the available options, under some kind of standard conditions.

If the source and load impedances are totally unknown, a 50-ohm environment is actually not a bad choice for a standard test, since it's neither extremely high nor extremely low. If you have a better handle on the practical source and load Z, then it makes sense to define a different standard test environment - for example, the standard Line Impedance Simulating Network (LISN) used for AC line/mains filters has a much lower source Z.

The common-sense solution is to have standard tests, but understand their limitations. Unfortunately - as Wes knows, all too well - military spec writers aren't noted for either common sense or understanding.

Where have all the VHF prescalers gone?

A project I am designing worked with the MB501 (SA701 / MC12022 / SP8704), but it is now obsolete.
I managed to find a few MB506 chips so board was modified to suite. Now the source has dried up.

I have searched the web, visited 1000s of sites, all without success.

Anyone have any suggestions for a DIL or SIL VHF prescaler chip that will operate to 146 / 150MHz?

Perhaps I can use a n SMD (1.27mm pins) on a little PCB that plugs into the MB506 socket? Any ideas?

The project is for education, so I don't want to stuff the complete synth in a single chip. The object is that all stages of the synth are accessible with a scope, or SA, for demonstration.

In fact the problem is that the receiver is less sensitive and
products a lot of whistles, even when I ONLY connect the output of the
VCO to the PLL, and control it with the potmeter (see
http://www.mcarsweb.com/_divers/3sketch.jpg).

That shows that the problem cannot be in the output filter of the PLL.

I have also tried to put the PLL circuit alone in a grounded closed
metal box to shield it, but I still get these whistles in the
receiver output.

Where do you think the problem could come from ?

I see others in sed have given valuable advice.

Seems like shielding will improve things. One other thing, try to power
the radio and the PLL from different sources just for a test. You'll need
good power decoupling to eliminate spikes generated by the PLL circuitry.

NEC 7F71RA (VHF tetrode from TV TX)

3SK183 DG-GaAsFET

The 3SK183 seems similar to the CF300 and 3SK97. I
would like to be sure about the pin-out, before I
power it up.

The only info I could find about the NEC 7F71RA
is on this page:
http://www5a.biglobe.ne.jp/~jh2clv/7f71radata.htm

Many Thanks.

Digi-key has a number of them from Infineon and NEC; On semiconductor
lists 8 in current production. I think all the through-hole ones will
have dried up because at those frequencies the package really gets in
the way of the signal, so you should probably plan on using SMD.

You can't actually win a war against an ism. Humans have been terrorizing
each other since the dawn of man and will continue to do so until they
become extinct. We use it ourselves against our enemies whenever the
need arises. The current use of the the words "war on terrorism" is
designed to get a soft-minded public to support the government's effort to
secure
the last vestiges of middle-east oil, and has very little to do with defending
ourselves against Muslim religious fanatics.

To generate a tone out a sound card is half a dozen
lines of C. To generate two tones isn't much more.
Look at any reference on how DDS chips work to see
how.

Try again?

The "justice system" will make whatever interpretations it finds convenient; ditto for the FCC. But then they've got to justify those interpretations and the conclusions they draw from them.

I'm not a ham at the moment: my Novice ticket expired in 1964. I own an Icom 751 transceiver, and intend to use it. That is, I intend to use it _legally_, after I get a General ticket. But I'm not a ham now, and I do intend to use the transceiver to transmit. Care to turn _me_ in? On what grounds?

> Try to buy some lockpicks.

Lockpicks?

Easy, here in central Oklahoma: I walked into the locksmith's shop nearby, and ordered two sets: one for work and one for home. I'm the Officially-Designated Lock-Picker at work: open desks, doors, file cabinets, and cars on legitimate request. Most recently I got into a car that some idjit had left running and locked with the keys inside, in the middle of one of our parking lots, blocking the only entrance/exit.

I don't travel with my own set, lest some overzealous police type decide that I'm equipped with the picks to use as burglar tools, but I do open houses, desks, file cabinets, and cars for friends in the area -- again, after being _sure_ that it's a legitimate request.

That rx is one of a long series of 80/40 "band imaging" sets to come out of ARRL Hq. They were all designed and built by staffers.

Some ARRL Handbook projects were QST articles first, while others were "built for the Handbook" and never appeared in QST or any other League publication. Most were built by HQ staffers, but a few were "from outside".

IIRC the 2X4+1 was built "for the Handbook" and its designer/builder(s) is/are unknown.

W1DX was the Handbook editor in those times but he's SK now, as are almost all Hq staff of that generation except for W1NJM. It "looks like" a W1DX project to me, though that's just a guess. He was very interested in getting the most performance out of relatively simple receivers. His 1957 QST article "What's Wrong With Our Present Receivers" is a must-read even today.

Actually, if he passes the Tech, all he has to do is prove he held a Novice ticket in 1964 and he can be issued credit for the code. Then all he needs to pass is the written exam to upgrade to General.

>
> 73 de Jim, N2EY

I think you're right about it being from W1DX, and that it's one of many
using the same basic scheme. I have the 1961 Handbook, and it has the
same receiver. Plus, right before it a simpler receiver that shows
a strong similariy to the 2X4+1, the "SimpleX Super".

But I can almost picture the latter in a QST. It has a distinctive home made
dial, and I think I've seen it elsewhere.

And then I started poking around, and it doesn't look like they specify
the dates of the QSTs where the articles originally appeared. This seems
to be a policy that varied over time. I know a few years later, they would
tend to specify the date of the original article, but I'm not even sure if
it was completely common.

So I wouldn't completely rule out that the article did run in an earlier QST. It surely would not have been more than a few years earlier, since as you say this sort of receiver tended to appear regularly, and after a few years they'd have a more recent construction article to put in the Handbook.

If someone had the annual indexes from around that time handy, it would be real easy to check whether this was a Handbook-only article or not.

> That shows that the problem cannot be in the output filter of the PLL.

I see....Ok, sounds like the trouble is in the VCO itself or in how the
VCO is coupled to the mixer. Do you have access to a spectrum
analyzer? It is beginning to sound like the oscillator may have a dirty
output or what used to be called 'squeegging' (sp?).
Here are some things I would try.
Use a couple of resistors to set the DC voltage on the varactor to some
moderate value. Make double-dog-darn-sure that the DC voltage feeding
the VCO and the varactor are absolutely clean (with a scope).
See if problem persists. (Obviously you will be at a fixed frequency
here). If so, I would suspect the oscillator problem described above.
Perhaps less feedback, or running it at a lower value of Vcc might help.
I think you said that the basic rx worked fine with a different LO. Is
this the case? If so, check the output of >that< LO with a scope or RF
probe and see if your VCO output is a similar P-P value. Maybe you are
overdriving the mixer?

My gut feeling is that the problem will turn out to be a noisy DC
control line on the varactor or dirty output from the oscillator.

Best of luck. Lets us know what you come up with. Remember.....this
kind of thing builds character and troubleshooting skills! :)

These are just basic troubleshooting ideas, but might lead you to
something meaningful.

...on April 1st? The famous "Write-Only Memory" or WOM comes
to mind. :-)

The original question involved "Zo of a feedthrough CAPACITOR."

Capacitors rated in "Zo" of a transmission line? I don't think so.

I've never seen that in 55 years. Maybe you have?

Capacitors are rated first in Farads. Next in working voltage.

In "characteristic impedance?" I doubt it happened even once.

These oscillators are much more stable than TCXOs used in ham equipment,
but they are not always directly comparable. A TCXO will be stable from
the moment it's powered on, while an OCXO like the 10811 will be very
far off frequency until it warms up, which may take 2-3 minutes.

Most ham applications do not need the extra stability offered by an
OCXO. Test equipment is the primary application for these devices.

If you toss it out, feel free toss it this way. :)

Why don't you email the ARRL and ask them?

Henry

Some the guys around here use them on 10 GHz SSB.
You really need that kind of stability for that mode.
A TCXO is 100X worse. Another popular use is as
a "flywheel" with GPS, to get a very accurate frequency
source. Search on "HP Z3801" for info.

(I worked at the HP division that made these for 19 years.)

Hi, Thanks for all the emails and QST searches, it seems from all the mail I've received its very probable that W1DX was the author of the receiver project, I must admit I'm very impressed with its performance, I'd like to get a copy of the article that W1DX penned in QST "Whats wrong with our receivers" I gather it was a one page article, if anyone has it I'd be grateful of a copy, I have on previous occasions asked ARRL for various bits of info but never received any useful replies, perhaps I didn't get to the right person, thanks from Ron g3yuh.....

the crucial piece of information is that noise stays even when you have opened up the VCO loop.

looking at your setup, it appears to me that the noise can come from two sources, a) the VCO and b) the PLL. evidentaly, it is not from the VCO as your experiments prove. it is probably from the PLL circuitry. this is quite possible. the PLLs involve a lot of digital, noisy switching that can generate these birdies and spurs. however, these should stay well inside the PLL block. in your case, they are getting coupled back to your output.

there are a number of cures for this. all of them will work at a better buffer between the vco and the following PLL. the simplest solution is use a grounded gate FET amplifier between the PLL input and the VCO output. be careful though, such a configuration is almost gaurenteed to self oscillate. but that is easily taken care of. what you do is this .. solder the FET upside down with its legs sticking up. solder the gate to the ground with as small a lead as you can. then, using a thin copper sheet or an unetched pcb, make a sheild that is soldered vertically over the FET (with a cutaway to allow the FET body). keep the source and drain leads on opposite sides of the sheild. bias the FET for nominal current at about half the Idss.

if you have a copy of EMRFD around, you can check this design in the chapter on oscillators.

No, unless you're a member, they aren't very polite. I've been down that road too. I used to be a member, but their attitude chased me away. At a hamfest one year, I went to talk to the area rep and he blew me off like trash. SCREW THAT. I dropped the subscription and I told them why. He was there TO talk to members about issues. He was too busy with his buds - sitting there with him. How he got to be a rep, I'll never know. He sure wasn't interested in people's views or concerns. It's things like that - which help kill a good thing. He to me, is what I call - a "title" collector. Loves the title, screw the job that goes with it.

797. Is JB Weld Electrically conductive?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-10 10:39:56 UTC
From: Scott <acepilot@bloomer.net>
Message-ID: <cc-dnXpevp2hWnLdRVn-tw@bright.net>
Source record: 24979

I am modifying some DSS satellite feedhorns for use at 10 GHz.
Wondering if JB Weld is electrically conductive after it sets up. I was
thinking I would use JB Weld to build up the outside of the "waveguide"
since after boring it out to 3/4" will only leave a wall thickness of
about 1/16". That doesn't leave much meat for the two machine screws
that will be used to mount the panel mount SMA connector to screw in to.
That's only about 2.5 threads if I use 4-40 hardware or 3.5 threads if
I use 2-56. Not sure what size holes are in the SMA, which will dictate
which hardware will have to be used. God forbid if it takes a 6-32
screw to do the job (2 threads). The mounting screws can not penetrate
into the waveguide. Any other ideas?

Something else I just thought of...once the JB Weld has set up, will I
be able to tap threads into it?

Nevermind...I found the technical data sheets on the web. Is is NOT conductive after set up. It has iron filings in it, but since it is an epoxy, it is not conductive. The good news is that it CAN be drilled, tapped, machined, etc., just like any metal could be...the mounting screws should provide the "ground" connection once they are screwed into the waveguide itself.

THAT ought to provide a little inductance at 10 GHz.

W4ZCB

The SMA is 1/4-36. How about tapping for that and screw in a barrel mount?

==========

It is difficult to advise on enclosures if the size of the radio and front panel operating component dimensions are unknown.
However you can readily make your own 'taylor made' enclosures from scrap (preferably double sided) printed circuit board.
Result : a perfectly screened box with a neat appearance. To prevent the outside from getting dull due to oxidisation ,it is best to apply a matt varnish.
Ham fleamarkets are a good source for scrap PCB ,normally sold by weight ,at least on the european continent.

One of the great things which the telecom bust did was to make the equipment you designed at HP available to us experimenters -- I use my HP3586C Receiver's ovenized oscillator to drive my HP5334 frequency counter and HP3336B Synthesizer. I never dreamed I could have afforded this type of equipment until EBay made it possible.

Yes, that also sounds for me the best thing to do (improving buffer
between VCO and PLL). Well, I'm not experienced with such circuits, so
could you just explain how to bias the FET.

```
VCO o-||-- S-D --||--o OUT TO PLL
^ FET=MPF102 or stg like that
G
|
o----------------o GND
```

And one last thing, could you re-explain how you advise to shield the
FET ? I don't see what you mean :-(

Thanks for your answer ;-)

The first thread in news:alt.off-topic would have to be a discussion
of what posts are ON topic for that group.

Or people could just set "followups to" directed to that group from
every other group.

73 had some good projects. Believe it or not, I started collecting
parts for a scope project in the nov '75 issue. It's
still under construction from time to time. By now I have all
the parts, and even etched the circuit boards. Interest has
wained from time to time since I now have a good tek scope
but I'd still like to put it together someday!

This may be an Urban Legend, but.....

Has anyone ever run into or hear of a situation where a radio "from the
good old days" of steel chassis, would not work when built on an
aluminum chassis?

It has been some time since I heard that, so I do not recall the
details. I suppose it might have something to do with inductance or
magnetic fields???

Curious minds, and all that...

I agree.

Probably all tied up in the Chapter 7 process right now, but the
rights to selling back issues, on paper or on CD, would be a saleable
asset of the magazine.

It may take a couple of years for them to be sold to an outfit which
would be able to publish them, but there is certainly enough interest
in a narrow market to make it worth someone's while.

In theory, someone could also buy the rights to the magazine itself,
and restart publishing 73.

Back in 1965 when I first got my ticket, people were saying that I should join and help change the organization rather than refuse to join. It's been 39 years, and all those people who stayed to change the organization haven't changed the organization.

I was the project manager of the 5334B frequency counter.
It had an option to have a 10811 timebase. The standard
timebase, which I inherited from the 5334A design was
embarassingly bad, barely able to do 10 PPM. Unfortunately,
you cannot retrofit a 10811 to a 5334, because you need an
extra PC board. This board is required to be able to put
the 10811 on its side, because there isn't enough height for
it.

The gray market in used HP/Agilent test equipment is
really hurting Agilent in some products. My old division no
longer exists. I now work at Agilent Labs.

Interesting. Could you shed some light on the timebase used in the
8566B and related analyzers circa 1984? The one I'm looking at doesn't
appear to be the standard 10544 or 10811 unit. I've never run across
one of these before in any other HP instruments. Is it just a
repackaged 10811?

Rick,

The 10811 that I have has a decal on it that reads "upgraded to series
3010". Do you know what that means?

thanks,
Lefty

Used equipment is NOT a "gray" market. Anyone who buys an
expensive piece of equipment is entitled to sell when they no
longer have a use for it.

The various versions of 10811 have part numbers
of the form 10811-6XXXX. There are a few dozen
varieties. I've never heard of "series 3010" in reference
to 10811's.

I'm guessing that the 8566, being the flagship product, used the
deluxe version of the 10811 with RF connectors instead of
the edge card connector usually seen. The
two versions were designed with A and B suffixes originally,
and later with D and E suffixes. (I don't know what happened
to the C suffix). Inside the shielded box, the oscillator itself
is a normal 10811 series.

Regardless! In a lease purchase, the leasing company has the
option to recover the property. If a bankrupt judgment was made,
it was sold as a tangible asset, no difference. However maybe it
IS an indication the price was too high? (If it bankrupt the
company.)

<< Hi, I have an old crystal unit quite large about the size of an average octal valve, metal circular, >>

Ron-

Does the cover come off? Are there screws holding it onto the base? If it isn't a hermetically sealed unit, it might be a crystal oven with a heating element and either a thermostat or proportional temperature control. Such an oven might have just about any frequency crystal inside.

If the unit is hermetically sealed, it may not be an oven, but could be a temperature-compensated precision crystal, perhaps something like 100 KHz or 10 MHz.

The 10/X C/2 doesn't ring a bell to me. I would examine the surface more closely and see if there is any other text painted, stamped or engraved anywhere on its surface.

Lefty-

The 10811-60111 that came in my used HP 5334B counter, had a blown thermal fuse. Upon considerable investigation, I found that it was a common problem and had been addressed by HP, using fuse with a higher temperature rating. It is possible that your 3010 refers to the thermal fuse upgrade.

Incidentally, the going price for a used 10811-60111 was around $100 a couple of years ago. I trusted a guy and ended up with a second unit that also had a blown thermal fuse!

Possibly it refers to a production change that took place in the 10th week of 1990 (=60 + 30), in HP date code.

Magic stuff, It will take tappings without problem, so long as there
is the material around it sufficient to hold it.

Strangely, here in UK, JB Weld is no longer available. I have a few
spare tubes and was asked if I would sell them to a local engineer
because he could'nt source the stuff anywhere.

830. WTD: HF Dummy Load for servicing

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-11 09:58:03 UTC
From: Gregg <nospam@unknown.org>
Message-ID: <La8Ic.32613$eO.22466@edtnps89>
Source record: 24912

I find myself a TV tech, getting dumped on with older HAM rigs for repair
by newbie licenced HAM's with no vacuum tube experience.

I am in need of a decent 50 or 100 watt dummy load to properly align the
transmitters at full power.

I have stuff for trade or am willing to pay up to $20/USD for one shipped
to Canada, postal V0X 1X0.

Lemmie know if anyone can help :-)

My real email is geek <at> scorpiorising <dot> ca

Thanks all,

Outside of the usual ones on e-bay , as long as it is a tube transmitter you
can use a 100 watt lightbulb. While it is not a very good 50 ohm load the
tuning of a transmitter should let it work.

==========
Assuming that the HAM rigs you get for repair are for the HF bands (up to 29.7 MHz) and this being a radio homebrew NG ,may I suggest you make such a dummy load yourself.

Ingredients :
- 20 pcs 1KOhm-2W - 5% carbon- or metal-film resistors
- 1 pce Cacoa (all metal) circular tin or similar for example a paint tin.
- 2 pcs Jam jar lid having a diameter slightly less than the opening of the tin .
- 1 pce SO-239 socket with square flange and 4 holes (+ 2 suitable screws/nuts/seal washers) to suit PL-259 coax connector
- 1pce 150 mm (6inch) long thick copper wire ,dia 1 to 2 mm (not critical)
- 2 pcs Metal stand-off each having 2 tapped ends with screws (length 25-50 mm).

a) Drill 20 one mm holes (equally spaced) near the edge of both jam jar lids and tin area around the holes on both sides.
b) Drill a concentric hole (16 mm diameter) in one of the jam jar lids and a concentric 2mm dia hole in the other
c) Drill 2 pcs diametrically opposed 3mm dia hole in the lid with the 16mm hole using the SO-239 socket flange as a template.
d) Drill 1 concentric 16 mm dia hole in tin lid and after that use the SO-239 socket flange as a template to drill 4 holes (dia 3mm)in the tin lid
e) Fit the 2 stand-offs to 2 diametrically opposed holes in the jam jar lid with the 16 mm concentric hole with the lid's inside surface towards the stand-offs.
f) Cut resistors' wire ends leaving approx 5mm on both ends
h) Protrude remaining resistor wire ends through tinned holes in lid with fitted stand-offs and solder.
i) Do the same with the other jam jar lid (the one with the 2mm dia concentric hole) by pointing the lid's usual top towards the resistors and solder these to usual inside of lid . The 20 resistors are now sandwiched between the 2 jam jar lids .
j) Solder one end of the thick 6 inch long copper wire to the SO-239

connector and fit this connector with 2 diametrically opposed
bolts/nuts/washer to the tin lid
k) Protrude other end of 6inch long copper wire through concentric holes in
resistor package and fit the 2 stand-offs to the 2 remaining holes in SO-239
connector flange.
l) Finally solder copper wire to now bottom jam jar lid and cut-off excess
wire.

By putting the package inside the tin you now have a 40 Watts dummy load
It should be obvious that the resistor package must not make direct contact
with the tin.

You can increase the power rating of the dummy load by filling the tin with
oil . I have used motor oil for the past 18 years in a particular dummy load
with the resistance changing from 49.8 to 50.6 Ohms over that time.

However before using oil I would recommend sealing the tin's seams with
epoxy glue (the 2 components stuff) on the inside to prevent 'oil sweating
' through the seams.

With all the ingredients and required tools available ,the above should be a
1 evening's job.

Measured SWR (with MFJ 259B antenna analyser) is 1: 1.2 @ 29.7 MHz and
less at lower frequencies.

Although it is unlikely you will be testing the transmitters at full output
for any length of time ,the above dummy load will happily absorb 100 Watts
for 15 minutes if accommodated in a tin of not less than 1 litre (about 1
quarter US gallon)

Good Luck with this simple homebrew project.

Frank GM0CSZ / KN6WH

Gregg-

Take a look at http://www.mfjenterprises.com/products.php?prodid=MFJ-260C for a dummy load that will withstand 300 watts for 30 seconds, or 25 watts continuosly.

It costs about twice what you mentioned, but is less than similar Bird models. If price is important, search E-Bay for dummy (load,antenna).

I've used IR lamps a few inches away from the FC
to heat it, works FB! I've also heard of people
using fishtank heaters (modified to short out the
regulator) as heaters in the etch bath.
Rocking the etch tray also helps, I've built a
rocking stage using a cam and a low rpm motor.

On a related subject...
As anybody used those iron on transfer sheets to make
pc boards using a laser printer or photo copyier?
There was a brand call blue..something or something..blue
I forget the exact name. I used a sample of this a few
years back and it worked much better than the kind that
relied only on the toner as resist.

What you want is the Heath 'Cantenna'. These show up on ebay
from time to time. Back in the 60's 70's, and 80's almost every
ham had one so they are not very rare. They do have a small
problem, the brass bands that attach the resistor element to the
unit break in half after many years of use (either from metal
fatigue or chemical reaction to the 'oil') and will have to be
replaced. Small hose clamps may work, or you will have to make
your own from sheet brass. Also many of these were filled with
'transformer oil' obtained from the local power company. While
this stuff had ideal thermal and electrial properties for the
job, it was a hazardous chemical that shouldn't be allowed to
get on the skin, or disposed of to seek into the ground water
table. (CANCEROUS!).

An equivalent to the Cantenna is still being sold by MFJ Enterprises.

That's what I ended up using after I boiled the water in my
immersion-cooled 47R/2W resistor, but didn't know if that was sufficient
;-)

Thanks.

Thank you!

Aye, I sure can DIY and have done those, but I was very lazy this time and
just took a boo for one that might be available ;-)

I like yours and Fred's ebay suggestion best and will go with one of
those.

Thank you all for your replies!

Take care,

I've used Press 'n Peel Blue film, it works fairly well. Glossy paper works
just as well and is a lot cheaper. I use the standard UV exposure technique
with very good results.

Hi Group,

I have a small box that is made by a company called ascom. It appears to be a vintage item from around the 70's. It has two push buttons for selection of channel 1 or 2.

On the back is a connection to an HF rig and the unit is suppose to mix down freq in the range of 30-50 MHz and be used with an HF rig has an IF to receive signals in the 6 meter band.

Anyone remember the Ascom? Anyone have a schematic?

Source record: 24926

Some brand new composition resistors followed me home from a fest
today. More than I can use! I have 50 to 100 of each value. These
are
Allen-Bradley 5% just like used in the original equipment. I
have the following:

47 ohms, 390 ohms and 1200 ohms--- all 1/2 watt

15 ohms and 180 ohms --------- all 1 watt

All are still in their plastic wrappers. Will trade for your excess
or
sell if you don't have anything to trade.

Thanks,

Bill

hi all,

if you ever need replacement mineral oil for the dummy loads,
stop by the local veterinary supply house, the have it in
gallon bottles about $ 12 or so, and no funny looks.

It is used on the farm and for livestock so low cost.

let me explain this a little more visually.

to begin with, i imagine that you are building this ugly style over a
copper clad board. Now, imagine that you have soldered another piece
of copper clad board (about an inch high and 2 inches across) so that
stands vertically at ninety degrees from the base board.
Now imagine that you have cut out a small mouse hole in this 'wall'.
The size of the mouse hole is just enough to let the FET's body (and
not the leads) pass through.
You take an FET, bend its drain and source to ninety degrees and away
from the FET body. Now you slide the FET into the mouse hole. Bend
down the gate and solder it to the base copper clad board.The source
and drain leads should be on either sides of this wall (the sheild).
this will prevent the source and drain from coupling the energy back
to each other.

Hi Bob,

I don't know if this has already been posted, I tuned into this thread a
little late, but you should check out this link:

http://www.fullnet.com/u/tomg/gooteepc.htm

I was using transparencies from the local copier place, but this method
seems to work much better.

AFAIK, the 3010 sticker has nothing to do with the thermal
fuse issue. The thermal fuse was a debacle from the get go.
If your fuse fails, just replace it with a piece of wire. Ovens
very rarely run away. It is far more likely the fuse will fail
or its socket will corrode (can't solder it in because the solder
would melt the fuse). If the oven does run away, the heater
transistors will open up and serve as fuses.

853. New Program - XTL_SET.exe

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-12 15:44:23 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <ccubkn$8fi$1@hercules.btinternet.com>
Source record: 24935

New program XTL_SET.exe

About 60 kilobytes.

This program is both practical and educational. It is based on two loosely-coupled tuned circuits. There are several applications. The circuit of a 'crystal set' is illustrated. Tuned circuit L and C settings and the coefficient of coupling between the two coils can be varied from the keyboard while observing how signal power and voltage levels change at several points during a tuning-up operation.

The signal source is a broadcast transmitter of adjustable power output which radiates a groundwave. The radio path distance and ground path resistivity are also adjustable. A simple inverted-L receiving antenna of given length provides the signal for the receiver.

Download XTL_SET in a few seconds from website below and run immediately.

A slight variation on this approach, which I've seen recommended for
use with U310 (TO-52 metal case) is to actually drill a small hole
downwards through the "ugly-style" copperclad, just barely large
enough to admit the body of the JFET. Drop the JFET into the hole -
it's fine if the metal case contacts the copper, as the case and gate
are connected together. Bend the source and drain out sidewise, leave
the gate lead sticking up in the air, put the shielding piece of
copperclad with the "mouse hole" into place, solder it to the board,
and then solder the gate lead to the copperclad on one side of the
shield.

This results in a very short, low-inductance connection of the gate to
ground.

This technique would probably work just about as well with a J310 or
similar TO-92 plastic-package JFET, although it won't give the
additional benefit of grounding/shielding via the metal case.

As to the U310 - anyone know of a convenient source? I haven't seen
anyone selling old-stock U310s on the Net, and there's only one
manufacturer I know of making them (Linear Systems).

I'd always assumed it was there to avoid heat-damage to the expensive
part (the crystal). Unfortunately, it was mounted far outside the
thermal enclosure for the crystal and its oven, so it's unlikely to
detect any failure condition short of a house fire.

Rick-

I've seen photos of these ovens on E-Bay, that had been stained by smoke coming out of the adjustment hole. I'd rather have some kind of protection.

I believe the oven uses proportional control, so the transistors' maximum dissipation would occur when the heating element is half on. In a "runaway" mode, the transistors would be switched on with maximum current but nearly zero voltage. Also, one transistor failure mode is a short-circuit.

With regard to John Miles' comment about the thermal fuse being to far from the oven's heating element to be effective, perhaps that is true. However, the earlier thermal fuse was rated at 108 degrees C, and it occasionally would open in an oven that was apparently operating correctly in the range of 80 to 84 degrees C. The newer fuse is rated at 115 degrees C. I suspect the problem is that it is opening due to a combination of time and temperature, not temperature alone.

I've been running one of the new parts for about two years without a hitch. The frequency has not been adjusted since about two years ago, and it still takes 15 or 20 seconds to drift one Hz against a 10 MHz rubidium oscillator.

That HP 5334B is one nice counter!

W7ZOI has a quick and dirty way of finding this out.
1) Connect a 1K resistor from the drain of the FET to 12v power
supply.
2) solder a 10K resistor from the source of the FET to ground.
3) ground the gate
4) apply power and measure the voltage on the source. this gives you
the pinchoff voltage (Vp).
5) short the source to the ground as well. Meausre the current flowing
through the drain (you can measure the voltage between the drain and
the 12v supply and divide it by 1000). This current value is IDss.

Now, choose a source resistor of the value Vp/(Idss * 4).

btw, you can simpley chuck all this and try 560 ohms. it should work
;). the gain, noise figure etc are not too crucial. the idea is to
buffer the input and output.

Okay, but that stuff is only used to find out the Vp and Idss I guess ?
So the "amplifier" itself is only made up of the FET, with the gate
grounded, the drain as output, and the source as input via 1 resistor (560
ohms) ?

Damien

PS: that's probably the last question ;-)

Well, I built it. It gives an SWR equivalent to having an unterminated coaxial cable - in the order of 1:6 or 1:10, i.e. the maximum that I can measure. I first tried it with 10 m coax, about half wavelength on 20 m, then I thought I would try it with around a quarter-wave (~5 m) to transform the high impedance to a low one. That didn't help much.

However, my K2 antenna tuner can tune the antenna with 5 m cable and I can hear signals - even a rare one like OJ0 (not too far from LA-land!), but it is several S-points under my 75 horizontal loop in signal strength. I haven't tried to transmit yet.

867. Question on Picokeyer & Paddle

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-13 11:08:35 UTC
From: null1969@yahoo.com
Message-ID: <479c2105.0407130308.61d74908@posting.google.com>
Source record: 24849

Hello,
I am getting back to ham radio and homebrewing (qrp) after many years. I wanted to start by building the simple low power Picokeyer given in http://www.arrl.org/qst/2003/12/0312038.pdf
I am currently in India and the MOSFET 2N7000 is not available here. The article says that I can use a 2N2222 with a current limiting resistor in the base or emitter. Can anyone help me with what resistor value to use? Also is there an older MOSFET that I can use instead of the 2N7000 since a MOSFET inherently uses very low current? Electronic parts are fairly inexpensive in India but only the older and more generic/popular ones are available.
Also has anyone enhanced the original software for the picokeyer in open source/freely available form?

I am also looking around to purchase a good paddle for qrp work (both qth and mobile) in the USA. I know from my previous stint in the hobby (qro) that Bencher paddles were just about the best, but they are also a little pricy - they have gone up 50% since the last time I checked. Is there a below $100 iambic paddle that is good for home and mobile use?

Please post your replies.

Thanks & Regards,
Jay

Do you have Home Depot stores in WI? HD carries it locally, and I would think it would be there since Home Time on Public TV is a big supporter of that show. Isn't that show out of Wisconsin? I hope JB Weld hasn't been discontinued. Gosh, I'd miss that stuff badly.

Thanks for comments!
An the funny thing is that oscillator fed from 74HCU04 (4 of 6
inverters in paralell) with 0.1uF coupling capacitor, with 18.56MHz
xtal filter on the o/p and a lowpassfilter on the input the IP3
increases to +25dBm, and when the 180 ohm resistors are reduced to 120
ohm the IP3 increases to +30dBm. At last the supply voltage for
74HCU04 was increased to 7V and IP3 is measured to +35dBm.
It seems to be an advantage to use the LPF on the input, while it
would totally spoil the performance for a ringmodulator

There's just not enough VHF homebrew out there! Particularly since
there's all sorts of wireless semiconductors that cover VHF at their
absolute lower limit (we won't get into why there's no UHF homebrew
given that's where all the wireless chips are).

"QRP Classics" has a little bit of 6 meter stuff, as does "Solid-State
Design for the Radio Amateur", but I haven't seen much any where else.

Seems like a self-resetting "Polyswitch" overcurrent limiter might be
a workable alternative. You'd probably want to pick one whose "will
pass" current is somewhat above the highest amount of current that the
oven would draw when it's quite cold. If the transistor shorts, and
the oven draws more current than that, the polyswitch would heat up
enough to go high-Z and chop off the current. Cutting power for a
minute or so would reset it.

I think you'd need to experiment a bit, to determine how much current into the base is required to turn a 2N2222 on hard enough to key your rig reliably, while still using the least amount of current. 3k0 in the base leg would be low enough to turn the 2N2222 on quite hard (it'd put 1 mA into the base), but this is probably overkill (the rig's probably not going to require more than a few mA to key up properly, I'd guess). I'd suggest starting at 10k0 and working upwards, until you find that the rig no longer keys up reliably, and then go down a bit.

You might want to try a pair of 2N2222s in a Darlington arrangment, with a high-value pulldown/turnoff resistor between the second transistor's base and ground. This would let you use a high-value resistor between the PIC and the first transistor's base (47k or higher). A Darlington pair would be slower than a single transistor, but unless you're in the thirteen-gabillion-word-per-minute class I don't think it'll matter in this application :-)

> Also is there an older MOSFET that I can use instead of

They probably are available, but you're going to have to look to see what the MOSFET's threshold voltage is. The Picokeyer uses a very low battery voltage, and you'll need to pick an enhancement NMOSFET which will turn on reasonably well with only 3 volts on the gate. A lot of the older MOSFETs require between 5 and 10 volts to turn on solidly.

Now, without spending five hours of quality time with my local FCC rule book, which could be more profitably spent working on the 6 meter R/C receiver that I've got cooking, I can't say for sure that you're wrong.

But if you were here I _would_ bet you money (which I never do) that the no code license does _not_ restrict you to commercially-made equipment -- you're supposed to know your own limits, but with them you can go like gangbusters. Can you point to a specific rule that shows that I'm wrong?

As near as I can tell the vast majority of folk with a no-code tech license are either disinclined or unable to build their own stuff, but not forbidden -- which is worth it's own rant.

How does the no-code license restrict you to commercial gear? I see nothing in the rules that says this. After an absence from Amateur Radio of 38 years, I bagged a no-code Tech at a hamfest in 1998 and proceeded to build myself a 2m rig from a TenTec kit. Did I break the law? I don't think so. I have since re-obtained my General but passing the code again didn't make me technically smarter.

Hi Alex,

I found some interesting vhf HB stuff at JF1OZL's web site:

http://www.intio.or.jp/jf10zl/

He is a prolific builder and apparently very good at design.

Also, while not exactly what you asked about, Far Circuits
has a pc board for the Nor' Easter 6 meter AM transceiver.
Speaking of that, 6 meter AM was BOOMING into central Kentucky
from northern New York and else where this past weekend.
Copied many guys on AM (!!) with my handy-dandy Radio Shack
scanner and an attic mounted antenna. I couldn't believe it...

73,

phil

Your "rant" would make more sense if you'd stated that you were here in
Canada. Most of the world won't have a clue what you are talking abnout.

And, the fact that in Canada one cannot use home made transmitters until
they pass the advanced test likely is not a significant factor here. Canada
is a small country, and over the years there's rarely been technical material
published in the few Canadian ham publications. So we look to the US and
the UK for technical material, and they don't have such limits on what
one can build.

There is actually a lot of HB associated with VHF, but the effort just doesn't happen to go into building QRP transceivers.

Code proficiency is totally irrelevant to that. Some of this country's most advanced VHF homebrewers have held a no-code licence for over 30 years. The same is true in Germany, France and several other European countries.

>You can also use a tranformer's single winding with a centre tap .

Thanks, Frank. Turns out on further investigation the circuit
specifies * two* 32 ohm insets in series for 64 ohms altogether. I've
still only got an 8 ohm earpiece, though. So that's an 8:1
transformation which adds up to.... a tap a quarter way along one
winding? Or is it three-quarters. Or of course a full, 4:1
transformer, I suppose. I always get confused with transformations,
for some reason. :-/

Hi
Anyone got a spare IN34A diode for an Rf probe, or can recommend a similar diode?
I wish to make an RF probe for measuring rf voltages in my transceiver.

Not strictly home brew - but Ten-Tec offers a transverter kit
for 20 meteres to 6 meters. The kit is readily and easily
modifiable for 10 meters to 6 meters - I did it, as have others.
And there are 10 meter all mode radios at hamfests typically
about 125 - 150 bucks. I got one that was broken for $50 -
all it needed was an electrolytic capacitor.

Any small transformer with a winding ratio 2 : 1 . Check with low
voltage -50 Hz , 1 V in ......0.5 V out. Ratio is not all that critical .
You can also use a tranformer's single winding with a centre tap .

==========
In the UK a Foundation Licensee (entry level) is not permitted to operate a
homebrew transmitter except when it is an approved kit.
This means he/she can not build and operate a transmitter from a published
design with bought components ,but is allowed to build a transmitter with
design and all components supplied by a reputable 'kit-house'.
As so often with this type of rules ,proper policing is hardly possible .

In the very early days of newsgroups (musta been in the early late 1980's -- back when I had a Compuadd 286-25) there was a post put together from an HP Engineer and an HP Sales Guy -- to the extent that you could order a tuna sandwich, 8566A, but mayonaise OPT-010030 was an additional $0.30, if you wanted the sandwich sliced, that was OPT-010031 for which you had to pay $0.05. Of course, you could have the sandwich diagonally sliced, and on and on.

If you filled out your registration cards you could get updates on the menu, but once tuna fish sandwiches were discontinued spare parts could not be reordered.

The winding ratio goes as the square root of the impedance ratio,
because you're transforming the current UP at the same time your
transforming the voltage DOWN. So you need a root-8:1, or about 3:1.

Yes and no. Agreed, code proficiency is not related to the ABILITY to do
homebrew.

If, as I think is true , the authorities (Canadian) forbid you to use a
homebrew transmitter with a no-code licence, it is wrong to say that code
proficiency doesn't come into it. OK, you could build the transmitter, but
it would be illegal to use it. As an aside, I wonder what happens to a US
no-code ham with a homebrew transmitter who operates in Canada....

No, code has nothing to do with it.

It's the written test that determines whether or not someone can build their
own transmitter, or rather use it.

Up till 1990, there were two licenses, amateur and advanced, and each had a code test. (Oh, there was also the digital license, introduced in 1978, that required no code test, but was limited to only some VHF/UHF bands, and the focus was for digital work. It barely got noticed after it was introduced.) But then restructuring came along. The code test was spun out, and the test for the entry level license was apparently simplified. I've never really seen the new test, but the whole point of the restructuring was to make it easier for newcomers to the hobby. And for the basic license, it was decided that few were interested in building, so there was no sense making the test to deal with such details. The tradeoff was that you cannot use a home made transmitter with that license.

The advanced test allows for building transmitters, and higher power (a kilowatt instead of 250W), and I think it is needed to run a repeater.

The code test was not required for either license, but then you could not operate below 30MHz. Hence, you could have an advanced license, but not have passed the code test, and the result was you'd have full priviliges, but only above 30MHz.

There were two levels of code test. 5wpm got you full privileges below 4MHz, ie 160 and 80 metres, but nothing else at HF. (I think that may have been changed, for more HF useage, but I can't remember.)

The 12wpm code test gave in effect full priviliges, minus the bits the advanced test allowed.

So it was rather a mix and match system.

Try Experimental Methods in RF Design. The ARRL position
it as the de facto 2nd edition of Solid State Design for the
Radio Amateur. I'm inclined to agree...there is tons of
stuff out there (my own library is growing steadily), but
people constantly complain of never being able to find
anything. I'm not sure where the disonnect is...

Reminds me of a conference I went to last year, where a
fellow walked by me with a copy of EMRFD under his arm.
I commented what a neat book it was, and when he turned
around I saw his name badge: "Rick KK7B".

In 2004 the obvious solution is a nice and stable LO
(easy), an I/Q baseband up/down-converter (ditto), and
some DSP code (also easy).

Yeah, that *is* worth it's own rant.

However, when I went to go for my no-code class licence here (Canada), I was told:

- without my 5WPM, I was restricted to:

1) 50MHz and above and
2) commercially made equipment

shrug

Sometimes, I wish I didn't let my VE4 lapse, which I did because of the HAM attitudes in Winnipeg in 1982 when I did let it lapse. But now I do see a use for it because I would love to help pioneer experimentation....something sorely lacking in many new HAM's because they can for easier/cheaper/less bother go to the store and buy an antenna, rig, coax and for an extra $50, have someone install the lot for you.

sigh

Hi Michael,

I wish our leaders would get off their fat, beaurocratic butts and
actually *lead* in the area of communications again.

I say *again*, because we were "t3h pwnz0r" the US and UK until the
mid-60's, in the electronics field.

As for publications, yes, the US and UK do lead. As much as I hate the ARRL's politics and attitude towards many policies, I have ARRL publications and they are my bible :-)

Too bad. HAM's were the communications pioneers, even the military used
them for R&D. Now with digital and satellites and stuff, who needs QRP?
Who really needs the HAM anymore?

Funny thing is, CB'ers regularily communicate globally with 4W AM, 12PEP
SSB and more R&D has been spent on "skip" antennas and other QRP aides for
CB, rather than HAM :-(

HELLLLLOOOOOOO! One does not need 2KW DC on a plate(s) to talk worldwide
on 21, 24 & 28 MHz.

I've been almost tempted to petition IC for a special "QRP" class
certificate "no-code" HF licence - the user *must* use homebrew equipment
and *must* keep DC input to the final at 5W or less. The catch is the regs
& theory the person must pass be at the advanced level.

Good Idea? No?

> Code proficiency is totally irrelevant to that. Some of this country's

I have listened to 2 meter communications in BC and Manitoba for 25 years
and other than repeater ID's, I have yet to hear one QSO or even a call in
CW :-/

Kits are a GREAT way, IMO, a new person can learn. Hey, when I was 6, I
learned from Heathkit! :-)

There are reciprocal privileges, but my interpretation is when
operating in Canada, one is required to follow (and be aware of) all
of the Industry Canada (equivalent of FCC) regulations.

If you see <http://www.rac.ca/regulatory/rcip.htm>

you will find the following:
"Americans operating in Canada, must abide by Industry Canada RIC-2

- A US amateur who is qualified to send and receive in Morse code at
a speed of at least 5 wpm may operate an amateur station in Canada in
accordance with the provisions applicable to the holder of an Amateur
Operator's Certificate with Basic, Morse Code (5 wpm) and Advanced
Qualifications.

- A US amateur who is not qualified to send and receive in Morse code
may operate an amateur station in Canada in accordance with provisions
applicable to the holder of the Amateur Operator's Certificate with
Basic and Advanced Qualifications."

Again, RIC-2 would be equivalent to Part 97.

> for some reason. :-/
==========
For a (lossless) transformer V*V/Z = constant , hence the input to output impedance ratio is proportional to the square of the voltage ratio.
For your 64 to 8 Ohms application ,hence 8 : 1 impedance ratio you need a small transformer with a sqrt (8:1) = 2.8 :1 voltage ratio (equals winding ratio). You possibly have a small transformer in your junkbox from a wallwart , those low voltage DC power supplies you plug into a wall socket. They often have a switch enabling different output voltages 3-5-6-9-12 V
The transformer inside has a single secondary winding ,which could be used as an auto transformer for your application.
Perhaps you can also wind your own transformer on a toroid from an old switch mode PSU or the like, say with 50 and 140 turns or a single winding of 140 turns with a tap at 50 turns. The actual winding ratio is probably not critical.
The impedance of your earpiece is only around 8 Ohms for a limited audio freq range ; it is usually specified for 1000 Hz

Good luck with you endeavours

I think there is a 1/2 dozen "true" CB shops left in Canada. The one here
in Vancouver looks very low on those seeking their rig "Peaked", because
they view them as n00bs and not worth their time.

Those running "footwarmers" usually only do so in the mobile, because of
our mountains.

<< Does any one know what an EK 1, EK 2b, or AK 8 is ? >>

Mike-

I'll look for an old catalog at work. The "EK" series was their Educational Kits, possibly something like a digital electronics trainer. I would guess the AK 8 was a power supply for use with the EKs.

I suggest you call Heath, which continued in the educational field after they stopped producing kits.

Okay, many thanks, Frank (& Tim). That should be plenty to get me up
and running. I've got some toroids that should do the trick. I assume
since you say it's okay to use ones from PSUs that loss isn't a
problem here. I've got some low-loss powdered iron RF types, but
they're probably too small for the number of turns required. Still, a
bit of experimenting is what it's all about!
Thanks again,

p.

923. Re: PLL for VHF receiver (see attached files)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-14 14:15:59 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <40F5401F.7050603@iinet.net.au>
Source record: 24753

There are a few possible sources of problems
(1) Power supply for the PLL and VCO - noise on these will appear in the
output. use separate supplies with ?zeners rather than IC regulators
(2) Is the amplitude from the buffer enough to drive the prescaler properly?
(3) Is the loop stable - how did you arrive at your calculations for the
loop values?
(4) The VCO tank seems to be heavily loaded - it has an output directly
to the Rx and a large (68p) capacitor to the varicap which is low Q.
This would make it noisier. Why not take the output to the Rx from the
buffer? (is that how it was originally?)
Also could you use a smaller cap to the varicap? (say 5p or less)

The runaway oven problem isn't caused by too much transistor
current, rather it is caused by the transistor staying on too long.
Thus a current based system wouldn't work. Also, in the case
of the 5334A, the power supply is barely able to supply minimum
current for warmup, so the oscillator couldn't draw more than
normal warmup current even if it tried. In the 5334B, I improved
the power supply so that it warms up the oscillator in half the
time or less compared to the 34A.

Well, I did a little better than you at 1.5 Kbits/sec but it still took almost 7 minutes to download the whole thing.

Don't expect any answers from qsl.net. I tried to sign up for web space several times and sent them email requesting help, but never received any response. I finally went somewhere else for my web space.

If you like, since I was able to download the files, I could email them to you. All the files together would be a little over 1 MByte.

Arrrgh! Neither can I. Sorry for posting a bad link.
You can get to it this way:
http://www.allelectronics.com/
Then put 1N60 in the search box at the upper right.

Maybe my article recommending the program has caused a log-jam!

Qsl.net can often be more like "qsb.net", so try again later.

You don't read the rules very carefully, do you?

Your certificate of proficiency is good for life. Unless you voluntarily return it or the DOC or whatever it calls itself these days cancels it (and you'd have to do something quite serious for that).

It's only the station license that you had to renew.

All you need to do is apply for a station license. And since everyone who had a license was grandfathered (well maybe not the few holders of the "Digital license"), you've got full priviliges even if you'd never gone for the Advanced license years ago.

Of course, I'm not sure what happens these days, since one no longer pays for a station license, and it's all one piece of paper. But I can't see them forcing you to retest simly because you never renewed your callsigne.

As for what's what now, you'd want to read RIC-24 (unless they renumber it as things change). My copy dates from July 1990, right after the restructuring. It clearly shows that the Advanced test gives you the ability to build transmitters, but code has nothing to do with it.

There is a guy who has been selling (Ebay) Lambda multiple output racked power supplies for next to nothing -- these are steel and weigh a ton. You can repurpose a Lambda supply for this purpose, just take out the Lambda regulators for your next solid state project.

It's also available at Orchard Supply (owned by Sears) here in the SF
Bay area.

The home page at http://www.jbweld.net/ shows no suggestion that it's
been discontinued. They list Autozone, Pep Boys, Home Depot, Ace
Hardware, and Western Auto among their national dealers.

A boating-supply store might be another option, for their "Marine
Weld" version.

> >> for some reason. :-/

Paul, maybe others. I don't know if this would help but I had to explain this "square root of" thing to some students who had some basic knowledge of DC and knew enough about AC electricity to understand a transformer stepping voltage up or down. And it seemed to help?

It went like this.

Draw two boxes on a sheet of paper to represent transformers.

The first transformer has an input of 20 volts at one amp; so the impedance (Volts /amps = 20/1 = 20 ohms.)
This first transformer has an output of 20 volts at one amp (forget about transformer losses and all that stuff) so the secondary impedance is also 20/1 = 20 ohms.
In other words it has a one to one ratio both for voltage and impedance matching.

The second transformer also has an input of 20 volts at one amp. 20 ohms again.
This second transformer has an out put of 10 volts at two amps. So 10/2 = 5 ohms. Notice that this is not HALF of the input impedance but one quarter; which start to give one a clue to what is happening?
The voltage ratio of this second transformer is two to one. That is 20/10 = 2
The impedance ratio however is 20/5 = 4 to one. Think about it!
Voltage is 2 to one, but impedance is 4 to one.

You can try it again with say a ten to one transformer.
Twenty volts at one amp input to, say, 2 volts out at 10 amps. OK?
Voltage ratio = 20/2 = 10
And the secondary impedance will be 2 volts divided by 10 amps = 0.2 ohms!
So the impedance ratio of this ten to one trans former will be 20 divide by 0.2 or 200/2 which is 100 to one!

So in all the examples the impedance transformation ratio of the transformer depends on the 'Square of the voltage ratio. Or;
Doing it the other way round the transformation ratio is the 'Square root of ......' etc.

Last example (Pause for breath!)
A 6V6 output tube has, say, a recommended out put load impedance of 5000 ohms?
To match that to a 4 ohm speaker the IMPEDANCE ratio is 5000/4 = 1250
So I need a suitable transformer with a TURNS ratio which is the 'square root' of 1250.
The transformer should have a ratio of 'around' 36 to 1. (36 x 36 = 1296).
And 1296 x 4 = 5184 which is very close.
Since this is an audio 'output transformer' voltage is not usually mentioned, except the ability of the transformer's insulation to withstand radio DC B+ voltages of 200 to 350 volts above chassis.

AIUI in practical radio work the ratio is 'not that critical'; since we are dealing with a range of frequencies and typically one or a couple of speakers in a wood or plastic box which may represent different impedance loads at different frequencies anyway; so in practice anything from 30 or 40 to one would at least be likely to work OK. Certainly to get a set working with a non triode type output tube working somewhere in the right region in regard to matching the speaker?

My first experience, at a tender age, was connecting some relatively high impedance, war surplus, headphones to the four ohm speaker output of a 1930s HMV and wondering why the sound was all "Wuffly" and distorted! I was rescued by my mentor (Elmer) my favourite uncle who set me on the right road. Ultimately I used a scrapped 'front door bell transformer' which had a ratio of roughly 240 volts to 20, (turns ratio 12 to one) backwards, to transform the approx. four ohm radio set output to something closer to my headphones!
If I can remember; volt/turns ratio was 240/20 = 20.
Impedance transform 20 x 20 = 400.
And 400 x 4 = 1600! And I think the head phones were 2000 ohms?
Anyway it sounded much better!
Sorry for the long 'rant'. Terry.

Yes, but we just take that 'ca' to mean that you're from California.

After all, if we weren't so US-centric we'd remember that there's more
countries on the American continents than the USA, and 'American' would
mean something a little more global.

Many thanks indeed, Terry. Set out that way, I'll have no trouble
remembering which way around it works in future,which will certainlybe
a first!
The only other question which arises is: having got the correct turns
ratio established; how does one determine the minimum number of total
turns needed to make a transformer that will actually give a
reasonable performance? For example, why pick say T50:T150 if you can
get away with T10:T30? The ratio in each case is the same, but I'll
wager there's a performace price to be paid by going for the
fewer-turns option! Anyone know?

From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <UilJc.23135$TB3.818776@news20.bellglobal.com>
Source record: 24778

I found some old postings that did not go into the how-to of cascading cheap ceramic filters in order to improve selectivity. I have a few 4-element and 6-element 455kHz filters with which I am experimenting in an IF downconverter for sound card DSP, specifically for DRM decoding which requires a nice flat 10kHz bandwidth. I'm wondering if it is not a good idea to DC couple them directly back-to-back. Should they be AC coupled? Should there be a terminating resistor to ground or a T-pad at the junction to provide a more uniform load/source impedance? Or is it best to make up for the losses and provide the proper terms by putting an active stage between them than having the gain makeup before or after?

TIA,
Tom

Pity.

I emailed KA5RUZ re the antenna. He emailed a very nice response
encouraging me to try it, but he gave no further technical info.

Oh, well. Maybe I'll give STLs a try when I can.

Andy

Welcome to the world of transformer design.

What you need to do is make the impedance of the winding considerably higher than the impedance of the load. For example, the winding connected to the 32 ohm load should have an impedance that's several times 32 ohms. A factor of 5 or 10 is generally adequate to keep the disturbance of the winding to a tolerable level, so shoot for about 160 - 320 ohms of impedance. You'll need to consult the data for the core you're using to determine how many turns that will require. Do this calculation for either winding -- the other will come out the same if the impedances are matched.

When you're dealing with audio and ordinary cores, the winding impedance will primarily be reactive, and the winding inductance will be fairly constant with frequency for a given number of turns. Consequently, the winding impedance (reatance) will be directly proportional to frequency. That means you need to do the calculation at the lowest audio frequency you intend to pass through the transformer. Capacitive coupling between the windings and other effects tend to interfere with proper transformer action at high frequencies, so high frequency performance degrades if you use way more turns than needed. Truly high fidelity audio transformer design is something of an art -- the audio output transformer was often a major limiting factor in tube-type audio amplifier performance.

And then somebody invented negative feedback.

Which, of course, continues to be used with transistor audio amplifiers
which don't require transformers.

We may have advanced beyond moving iron loudpeakers but the trouble remains
with loudspeaker fidelity - as it always did.

See my article at: http://www.karlquist.com/FCS96.pdf
Toward the end I show some cascaded ceramic filters.
You can't necessarily just cascade them directly. Of
course it would be ideal to have buffer amplifiers in
between stages, complete with impedance transforming
stages, since the filters usually don't work with 50 ohm
terminations. However, as you can see in the article,
there are shortcuts.

Bummer about the virus aspect... probably a good idea to stay away from
these titties.

At first glance the message seemed rather off-topic for radio
newsgroups. However, I suppose this unconventional use of silicon could
make it slightly on-topic. Silicone is certainly a more common material
for boob work. Silicon seems a bit hard and brittle for the task. The
new knockers must have been expensive, though.

Does anybody recognize the closing word? Looks vaguely Eastern-European.
How does one pronounce it? (I know... "just like it's spelled.")

Thanks, Roy. Looks like there's rather more to it than I imagined. :-(
I wonder if Reg has written a program to design impedance
transformers? :-)
I woke up this morning, having given it due thought overnight and
thought I'd got it cracked. But that was until you said the primary
inductive load Z should be many times the design load Z. Oh well,
back to the drawing board, I guess. Looks like it's gonna take a lot
more wire and a lot more turns than I'd thought. OTOH, I could just
stick an emitter follower stage on the end of the amp chain and have
done with it. :-/

Paul-

Now that you have a good grip on the problem, consider one more idea - that most audio amplifiers have more gain than they need, and operate with the volume control set at a fraction of full range.

If you were to use a series resistor (27 or 56 Ohms?) and NO transformer, would the output stage have sufficient power to produce an acceptable audio level with the volume control advanced?

How old are these filters - there was a design here in 1971 (The
Deltahet, using the Wadley Loop priciple) based around Murata 455KHz
filters - quite impressive specs, variable bandwidth, etc. Trouble was
the filters went hydroscopic fairly quickly, and I note that there are
very few (at least here) ceramic IF filters now available.

I instinctively doubt it, Fred, but I'm in a position to give it a try
so I shall duly do so! I'll report back the results later.
BTW, this isn't a conventional hi-fi type audio amp; it's solely been
designed for picking up very faint, distant sounds. I was intrigued by
the design so set out to further examine how it worked. I've spiced it
and have now built it; the last piece in the jigsaw is the Z-matching
problem.

I, and I'm sure quite a few others, would have recommended a simple transistor stage as a solution except for your request in the original posting about not wanting to suffer too much power loss. If your only concern is the amount of audio power you get out, and you're not concerned with overall power consumption, then an active stage is certainly an alternative. The type of circuit you choose would depend on how much efficiency you need and how much audio output power you require. An emitter follower is the simplest but least efficient; a comlementary-symmetry stage would be more efficient but more complex.

Oh, if it's something you built anyway, you might consider using something like an LM386 for the audio output stage. Besides providing considerable gain (which might eliminate some other stages), it'll drive an 8 ohm earpiece with no problem. And it's reasonably efficient.

Roy Lewallen, W7EL

Whenever I've played with PLLs I just put what looked like the best straight
line through the points and used the slope of that.

Use the geometric mean: sqrt(Kvco at low end * Kvco at high end).

At any given frequency your effective VCO gain will be the slope of the curve. If you really want to do it right you'll design your loop for adequate performance at the two endpoints, and everywhere in between.

If you're clever with the use of capacitors in series with your varactor you can flatten these thing out somewhat; if you get the frequency vs. voltage slope to the point where it varies by less than 2:1 then you can just design for the average slope and be safe.

Well using an op-amp did cross my mind, Roy, but it's cheating in my
book. I like to use discretes so I get a better idea of what's going
on and it's more of a challenge to get right!

THanks again. I note your comments but will try a couple of other
things first, whilst the initial assembly is still in one piece. One
such idea is the doubling or trippling of the supply voltage alone.
Does anyone know by how much it's safe to increase the 1.5V supply to
the mic insert and whether that might also cause distortion?

Source record: 24810

Thanks, Rick. Looks like a fascinating article - I've just read the part on the filters. As a starting point, I'll try two 6-element 455kHz filters with 1.5k desired source and load resistance and couple them with a cap scaled from your 22pF value. At 10.7MHz, I calc its X=680 or 2.06x the desired source/load of 330 Ohms. So 2.06 x 1.5k is 3090, leading to a coupling cap of ~100pF for 455kHz.

I did find this in an old posting by VE2BVW in the thread 'Cheap 455kHz SSB filters?':
"In an old article in 73 (December 1977) about the Yaesu
FRG-7, reference is made to an "by Ron Risher VK3OM in the March 1977
issue of "Amateur Radio". He describes... an alternate filter, consisting
of four cascaded SFD-455-B solid state filters linked by small coupling
capacitors".

In the same thread, from W7ZFB:
"Using the simple 5 pin 2 element SFD455 in series
makes a pretty good filter if the element coupling caps are
around 10pF. Two in series is better than some of the multi
element filters and four in series gets quite good.
More gets proportionally better."

His coupling capacitor seems awfully small for this frequency with an X of ~35k versus typical 1k5 to 2k specified source/load impedance. I would expect the attenuation through the filter to be very high.

Regards,
Tom

I'm looking at setting up my extra dual bander and my 10m rig in an old metal desk for base station use, and one of the local stores is closing out their old brand of 7AH 12V gel cell electric fence batteries. Given that each rig has a maximum draw around 8-10A at full power transmit, and few mA otherwise, that I won't be transmitting simultaneously on both, and that I will likely only have 500mA-1A of continuous charging current available, how many batteries should I plan to stuff in there? I do have the ability to charge at higher current temporarily if they become depleted during a power outage or something, but it's not convenient for daily use. (that charger has other uses that are generally more important)

Nope, live in Melbourne - Adelaide is very dry! - Melbourne is
miserably damp in winter - but we have had a drought for 10 years so
its not!.

Rick amended my statement, my experience was with 455Khz ones -
hopefully the 10.7Mhz ones are better and no doubt manufacturing
methods have improved in the last 30 years. Well worth a try -
although there has been so much published on using computer xtals to
do the same job is it worth the effort - depends on whats available I
guess!

6JS6 is the number that emerges from the cobwebbed long term memory -
used a lot in Yaesu stuff as pa tubes, ie 101's. Cheaper than 6146's
in those days, now the situation is reversed so the old rigs are being
modified to 6146's Unless you have boxes of them stashed away, dont
design anything around them, a long obselete technology...
73 de VK3BFA Andrew

PS - I have several dozen 807's in the junk box, will use them one
day.....

I've taken it up to 3V and there's a marked improvement in gain, at
any rate. I can live with it now. I'll still try the other ideas folks
here have had, though!

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday July 18th 2004
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

********** $1 buyers discount with hard copy of this notice ************

<<<<<<<<<<<<<<<<<<<<<<< cut here >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

Mail the coupon below by the 5th of the month to be a Prepaid Vendor.

FLEA at MIT 2004 Rates

SELLERS

This year each vendor must have a Cambridge Vendor License.
We will do all the paperwork to get the one day Cambridge licenses.
To keep the spaces affordable we are discounting your first space.
To use your spaces the named vendor MUST be present.
Rates include one admission per space.

Season Pass $99 First space includes $10 Cambridge Vendor License
$70 Additional spaces
Good for all seven meets this year.
Must be received by April 18th.

Advance $17 First space - includes $10 Cambridge Vendor License
$12 Additional Spaces
Must be received by the 5th of the month.

Gate Admission $20 First Space - includes $10 Cambridge Vendor License
$15 Additional Spaces
Admission is after the prepaid vendors

Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
** You may not sell. **
$15 per person at the gate.

Well, the difference in the US is that CB is now effectively
license-free (I think the legal side-stepping is that you have a license
by virtue of having the equipment). Makes it interesting when the FCC
wants to deal with a CB'er with a 1kW linear and "extra channels" up
into the VHF bands.

> linearity vs frequency?

Probably. I have seen some reference to GDT type ceramic filters which I think means something like Group Delay Tuned. Probably cost more and the range is more limited. Not sure how serious an issue this is for DRM or for any mode.

>
> Don't most AM broadcast radios contain ceramic filter(s).

Yes, probably also true, which is why gazillions were made and they are so cheap. But DSP filters are seemingly preferred for the most compact radios (e.g. cellphones) and for consistent, predictable performance with no tuning required, straight off the assembly line.

You could do a bunch of research on this. That's advisable.
Otherwise here's a general estimate: 4 or 5 batteries. In very rough
terms: while drawing transmit power, that's 2 - 2.5 amps per battery.
Figuring 5 batteries, say you transmit 20% of the time, and using the
radio for 1 hour. That's 12 minutes at 10 amps, so you use 2 AH
hours of capacity. Assume a charge rate of ~ 350 ma with the radio
off, and a receive draw of 350 ma - so during receive there is no
battery drain or charge. You need to put 2 AH back into the battery,
and charge efficiency can be esitmated at say 80% - so the total
charge must be about 2.4 AH. You'll need to charge for a bit over 4
hours for every hour of use.

Your 500 ma - 1 amp charger could support twice the number of cells
at 750 ma, cutting your charge time to a bit over 2 hours. With ten
batteries, you could run for 3 - 4 "transmit hours" at a 20% duty cycle
or about 20 hours total. That's figuring discharging the batteries 50 %.
You DON"T want to discharge them completely. In fact, you should
plan on including a low voltage shutdown circuit to protect the batteries.

Note how I'm getting you into bigger and bigger dollars. Say each
battery costs $10.00 I've run your cost from $40 or $50 to $100,
and that doesn't include cables, connectors, relays, whatever. That's
one reason it is more advisable to do some research. Another is to
get some real numbers on your batteries in terms of discharge rate,
charge time and so forth. How they are charged and discharged
has a direct bearing on their longevity. They are easy to ruin with
incorrect charging rate or too deep a discharge.

After reading an article about building an amplifier which used ten 1625's with paralleled RF but with series filaments directly across the 120-volt line, I've been saving them; hope to find the right round tuit someday....

Phase linearity or the lack thereof is a function of choosing the
right response (ie Bessel instead of Chebyshev). Ceramic filters,
cheap or otherwise, are nothing special in this respect. The
10.7 MHz ones were reengineered some time ago to have
better phase linearity, at the expense of stoop shouldered
amplitude response. This is optimum for FM (at least for
all pole filters).

news:2lqcmlFfj4gaU1@uni-berlin.de...
> And the difference between that and a CB licence is......?

No CB licence in Australia!!!

Seriously, the Aus. Foundation Licence will require limited Regs and similar theory as the UK Foundation licence. It will give access to 80m (less DX window), 40m, 15m, 10m, 2m and 70cm, at 10W PEP, voice or hand sent CW only (umm, with no CW test that is..), unmodified commercial equipment only.

And, for those taht haven't heard yet but are interested (for whatever reason):

Then we'll step up to the 'Standard' licence, which is our current Novice... Some slight reduction in theory and again, no CW exam, but all bands for foundation PLUS 20m, top half of 6m, 2m, 70cm, 23cm, 13cm and 6cm, at 100W PEP, may construct own equipment.

Last will be our Advanced, which will be our current full call, limited and intermediate. Again no CW but full regs and slightly more theory, all bands, 400W PEP, etc, etc, etc...

Cheers

That's similar to my ideas, which include doubling the 240V mains to 600V to put on the plates. an isolation xfmr would be needed for the filaments, tho.

600V at 4-5A would give a ballpark of 50 ohms plate resistance, low enough for no-tune techniques.

Still haven't found that tube # tho ;o)

If you are in the United States, you must have a License to operate that radio.

>I already read the online manuals for it but it doesn't even tell you
>how to do the most simplest things.

The manual does caution you about the License thing. If you do have the proper License, you can test the microphone by turning the radio on, pressing the push to talk switch, and speaking towards the front of the radio. If you can hear your voice in a receiver tuned to the same frequency as the HTX transmitter, then the microphone is working. Don't forget to ID when doing this test. Another easy test would be to contact someone on your local repeater, and ask them how the mic. sounds.

> --Myron.
Reminds me of an amp using a bunch of sweep tubes in parallel running
off the mains with a voltage quadrupler to get 600 volts.

With the 1625's there is a trick the old timers used to do.
Some brands of 1625's (I do not know which) had the beam deflection
electrodes ("grid" 3) brought out of the glass bulb with it's
own lead wire. (You might be able to see this upon close inspection
of the tube if the silver getter isn't in the way.)
The cathode and "grid" 3 were connected together
at the base pin. So what you did was to un glue and un solder
the base and then bring "grid" 3 out to it's own pin (there are
two un used pins on the 1625 base). This lets you run the 1625 in
grounded grid (cathode driven). Use 10 tubes, 9 in parallel as
the final, and the 10th as a driver stage. You now have a two
stage linear that will run about 500 watts out with less than
5 watts drive. The tube heaters could be run in series across
the mains, and use a voltage quadrupler to get 600 volts for the
plate supply. Use of an isolation transformer would be a very
good idea though!

I have seen a CB amp using as many as 12 of the 1625 tubes. There were 6 in parallel on each side of a push pull circuit. Not sure how clean the output was but they seemed efficiant enough to give about 300 to 500 watts out of carrier power and the modulation sounded good.

==========

Considering your experience with a wind generator ,destroyed in a storm , I am using a (only) 150 Watts wind generator in combination with 2 , 64Wp solar panels for my ham station + peripherals and desk lighting.

The wind generator make Marlec has a 'furling'tail meaning that up to a wind speed of 16 m/sec the tail is perpendicular to the rotor, meaning the rotor blades face the wind fully.
Above this wind speed the hinged tail moves off its normal limit stop and since it follows the direction of the wind the rotor blades are turned away from the wind direction and at increasing wind speed up to its other limit stop when (in a roaring storm) the blades hardly rotate. Living at a wind swept location in northern Scotland , my machine over the years has graciously survived a number of up to 160 km/hour (100 miles per hour) events.

Marlec also manufacture a larger furling machine the Rutland Furlmatic 1803 ,which produces a 60 Amperes charging current at nominally 12 volts or 30 Amperes at 24 volts.
By now they might have an even larger capacity machine.

==========
Considering that with so many valves (tubes) in parallel operation the
inter-electrode capacitance is multipled accordingly, it would be intriguing
to know up to which frequency this set-up could be sensibly used.

I have quite a number of 'never used' 807s in the junkbox , pardon me
.....NOS box.

Hi All;
I have 6 of these mystery grab-bag sorta sets of components & each has a construction box.
It took me many hours getting these so they all have about the same "stuff"
Most components are new, with some "clip-outs but all easily useable.
There are Mica, disc, other caps, BNC connectors, 9/12 volt relays, mica insulators, fet's, Chips, electrolytics, rectifier diodes, red single led's, peizo buzzers, xtals, trimmers, etc. Too much to list.
I hope the price is right?
I am asking $20ppd, shipping could cost me $5-6 depending.

This is hilarious. The OP asked a question. And asks it again:

What's the nomenclature for that sweep tube, produced just for Admiral TVs
years ago, that's heavier-duty than any of the other tubes?

I thought it was 6MJ6 -- but, no. It has an *octal* base.

Fella used to sell 'em in some of the mid-west hamfests, but I haven't seen
him for a while. Think his name is Don, and that he was also in to Racal
receivers.

1033. Elements for Cushcraft 2m Yagi

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-20 01:39:25 UTC
From: Jason Dugas <kb5urq@hotmail.com>
Message-ID: <10fotv37allhm80@corp.supernews.com>
Source record: 24715

I'm looking for some good suggestions on how to replace some broken elements on my Cushcraft A148-10 2m Yagi. They sell replacement parts, but I'm told that its cheaper to just use some welding rods as they are just about the same size.

I noticed that on the Cushcraft antenna the elements appear to be brazed(?) at the center into an encapsulation. At the center of the encapsulatoin is a hole drilled for the screw to go down through the element and into the boom.

How do would I recreate this if I were to use homebrew elements.

1035. Converting Vectronics HFT 1500 to L network?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-20 04:12:24 UTC
From: denton <denton@oregontrail.net>
Message-ID: <10fp6st9old4q04@corp.supernews.com>
Source record: 24717

Has anyone done this before? I am thinking of converting my HFT to an L network. I started by isolating the roller inductor from ground and re-wiring the caps in parallel across the inductor output to ground, but can't seem to have much luck getting the revised network to tune very well. Any ideas??

1036. Re: Sweep tube

The point is, that I don't know what the nomenclature is, and asked for help with it in the OP.

"Someone" mentioned this tube in a post "somewhere" several years ago. I've searched archives for faulty-memory-recollections of the nomenclature, to no avail.

For latecomer Noeding: I'd like to get enough of them to experiment with no-tune techniques, which might be practical with plate voltage around 600 and plate current of 4 or 5 amps. The "hilarious" comment referred to plain old thread-wander ;o)

There are 4 different combinations of L and C that can be used in a L network.
You might have yours in the wrong configuration for the impedance you are
attempting to match.

==========
Not owning/knowing the above type of antenna ,I might not be eligible to
comment.
However from your description re welding rods and its centre being brazed
into an encapsulation , it appears to me that a welding rod is too thin to
drill a hole through ,but by sliding over a piece of (stainless ?) steel
tubing ,with inner diameter slightly larger than the diameter of the welding
rod , and brazing this in the middle of the welding rod material on both
sides (encapsulation) you get an overall larger diameter through which a
hole can be drilled.

Well, I'd still endorse the idea of using 807, it is not so many other
6.3V tubes with the same socket, so you are more certain which type
goes there, and not at least - it was once mentioned water-cooling
(QST 1951??) - probably a good idea for those of you who like to tune
for very long periods to get the last microwatt into the antenna

It may be best to pick the least expensive "big" sweep tube for which
you have specs, and parallel enough of them to get the impedance where
you want it to be.

You should also be able to run the voltage down a bit at the tube's
rated current. This will reduce your power output but it'll reduce your
impedance at the same time.

If you use a 3:1 step-down on your output you'll load the plate with 450
ohms. This will require a 1.3A peak current with a 600V plate supply,
and should be good for 300W or more PEP output -- may be easier to start
there than at 5A!

of course, but still the impedance from each tube is high, and it does
not see 50 ohm or whatever load, and still you may need an antenna
tuner.

But I was pulling the leg, since it is not a problem for any moderate
intelligent ham to tune a transmitter. Since I am electronic engineer
and have been working with transmitters it amuses me to see that
colleagues don't understand about PLATE and LOAD, and have really
difficulties to tune a transmitter, other radio amateurs have
commented about the same. It is odd that you need to be an amateur to
understand how to tune a transmitter, and I have never seen it as a
problem, even when I started with a Starflite TX 38 years ago

Perhaps if the knobs were relabeled "TX" and "Antenna", and the plate
current meter was relabeled "reflected power"?

I see nothing wrong in principal with wanting to build a no-tune tube
transmitter, although it may be more work than building a
microprocessor-controlled transmitter tuner, and you may run into
insurmountable output-capacitance problems.

Can't really remember. Last time I had to assist it was Rohde&Schwartz
10kW 88.8MHz FM broadcast transmitter, and the colleague could hardly
achieve 1kW output, hi. Another ham worked at another medium wave
broadcast station in the summer 1960, and mentioned on an occasion
that "they had no idea how to tune a transmitter", they had some
different transmitters, incl. an old Marconi 10kW TX from 1933.

>I see nothing wrong in principal with wanting to build a no-tune tube

Well, I see 100pF output capacitance to cause some troubles on 450 ohm

Another problem is that all plate connections to a common point must
be measured to the same length. I am told this is really a problem,
even for a longwave transmitter, the reference transmitter operated on
360kHz as a console radio station, see my page

Usually, designing it to work well at both the min and max gain is the best.
Are you sure this is the only issue? PLL's have lots of sneaky closed-loop
response poles, and sometimes those are more important than the gain
variation.

Hi All;
I have 6 of these mystery grab-bag sorta sets of components & each has a construction box.
It took me many hours getting these so they all have about the same "stuff"
Most components are new, with some "clip-outs but all easily useable.
There are Mica, disc, other caps, BNC connectors, 9/12 volt relays, mica insulators, fet's, Chips, electrolytics, rectifier diodes, red single led's, peizo buzzers, xtals, trimmers, etc. Too much to list.
I hope the price is right?
I am asking $20ppd, shipping could cost me $5-6 depending.

impedance for 100pf on 14MHz is -j114, perhaps not so good in a 450ohm circuit

see http://www.noding.com/la8ak/12345/n12.htm for broadband techniques with ferrite transformers, and you could always read W2FMI's book "Transmission Line transformers", but I wouldn't use transmission line transformers myself

> > Thanks for your answers.

There are two considerations. In the low gain region the overall loop
gain is lower and the response will be slower. In the high gain region you
will be up against two things.

1) Any spurious coming down the control line will be highest on the VCO
output.
2) This is where you do you calculations for lock time as it will be the
most critical. THat is, it will be most prone to go underdamped and ring,
pushing the lock time out as well and creating opportunity for other
resonant-like effects.

It is better to design the VCO for a more constant gain characteristic.
There are a lot of techniques and trade-offs here though. There is also the
variation in the divider ratio, which also translates to loop gain change,
and has similar effect on loop response.

1056. The bi-polar transistor at RF

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-07-21 17:26:23 UTC
From: Paul Burridge <pb@notthisbit.osiris1.co.uk>
Message-ID: <8j8tf0dgs2qji2l2hglvuulndhqph1t0v2@4ax.com>
Source record: 24738
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Hi all,

Firstly, does anyone bother designing with Y-parameters *at all* these days?

Then... (talking of the common-emitter configuration in this case)
The only variable according to the Ebers-Moll transistor model apart from the device-specific "Is" which has any effect on Ic is the potental difference applied across the B/E junction. The signal voltage thus applied is loaded by the resistance of this diode. At DC., the loading is at a maximum and the entire PD appears across it. Right so far? As the applied signal voltage increases in frequency, the feedback capacitance (B-C) and the B-E junction capacitance form an AC bypass path across the B/E resistance above-mentioned. The two capacitances acting in concert shunt more and more of the applied signal voltage to ground, bypassing the emitter diode resistance, lowering the device input impedance and resulting in less and less applied Vbe across this diode and consequently less and less Ic output swing?

What I'm getting at is that Ebers-Moll is still good at RF, *provided* one allows for the bypassing of the emitter diode's resistance by the combination of Cb and Ce. Correct?
And CJC and CJE are the relevant Spice model parameters?

Thanks,

p.

Source record: 24739

I have an 422 keyer/paddle combo and had to cut the cable that goes from the keyer to the rig. My TT has an internal keyer, but my rockmite and ohr 100a 30m does not. I had to cut it because I wanted a "remote" keyer/oscillator. I rewired the innards to a 1/8" jack and the paddle itself with a 1/8" plug so that I could leave the bulky keyer somewhere else during field day as i did not need it. I want to be able to connect the keyer to my non-internal keyer rigs. I am confused though about the cable. This is going to sound ridiculous, but, do I need a 1/8 stereo plug or a mono plug? How does the cable work if only an RCA plug is used at the keyer(shielded but that is still only two wires)? How do I assemble an RCA plug to a 1/8" plug that I am assuming needs to be hooked up for stereo? I am so confused.

Any suggestions are appreciated

Hi
It seems to be some problem to build equipment to measure over
+35...40dBm IP3, and xtal filters seem to cause intermodulation
problem with this level

What I am after is constructions to build which works to measure
higher IP3. Would also be interested to see IP3 measurements for xtal
filters

IM3 is generally projected up from measurements made at much lower power levels -- on most RF circuits running at useful power levels the 3rd-order IM products vary as the cube of power, so you measure the power-in/IM3-out levels at lower input levels and plot it all on a graph.

Not that I can answer the OP's question, and padding down the signal is probably going to be a featured part of any setup.

True. Most systems will extrapolate out to IP3 pretty well, so take a
series of data points at lower power levels.

John..

Thanks for the websites.. I will keep them as reference..

Unfortunately an antenna tuner and a preselector are not exactly
the same thing as most people think..

But thanks for the information provided.. as a matter of
fact I am going to make a mini-tuner from one of your sources..

Thanks a bundle!

Well, let's see. You want the 3rd-order product to be above the noise floor of the receiver. Assuming a 10dB noise figure (you _will_ do better, yes?) and a 5kHz wide filter a -120dBm signal will be just discernible -- say you want it to be at least -100dBm.

With a projected intercept of 40dBm that gives you a 140dB difference; dividing that by 3 gives around 47dB down from 40dBm, which means that you need to feed about 7dBm into the receiver from each source (this is sounding pretty absurd, I should just stop now).

Oh well, persevere:

I think the issue is that you need to have some very stout sources, and a damn good hybrid combiner.

Not only do you need to make sure that each source's output won't bleed into the output stage of the other source through the radio connection and intermodulate there, you also need to make sure that note of the energy from source A gets into source B and visa versa.

The "amateur" approach would be to make two sources each capable of generating well over 7dBm (1W?) so that you can protect their outputs with attenuators. If I were doing this as a garage effort I'd make two identical crystal controlled sources, well shielded and operated from batteries (rechargables, if I'm going to be producing a frigging watt each).

I have no idea what to tell you about the hybrid combiner, other than you should pay attention to 3IM in the core, and test it.

Assuming that you have two good sources and attenuators, and a really stout hybrid combiner, you should be able to get clean, high-level RF into your receiver. At this point I'd take your RF (at what, 10 or 20dBm?), attenuate the heck out of it, and check the 3IM products. If you get a 3IM product that tracks the attenuation linearly then your sources or your combiner are at fault. If they track 3x attenuation then congratulations -- you're actually measuring your receiver!

Good luck. Maybe I'll stick to NE602's -- the measurements are easier.

It seems this is your field, while I've fallen off where math counts, hi. Agree that it seems somewhat absurd, just wonder how it is done to measure above 40dBm on the mixer input. Heard from some writers that xtal filters has an IP3 of 40dBm, andof the two 18.5MHz xtal filters tested, one homebrew and the other commercially made, the homebrew appeared to be the best, but the commercial filter had some rather small coils while the homebrew uses T37-2 iron dust cores with much less field. See notes about the Redifon mixer and the homebrew crystal filter on http://www.noding.com/la8ak/12345/n16.htm
The last mixer uses 4x HSMS-2802 and 3x 74HCU04

With an output of something near -6dBm from an U L Rohde type low noise xtal oscillator to an ultra linear amplifier, with say 20dB gain, it is somewhat low.
The constructions I have seen for measuring lower IP3 than in this case uses 20dB attenuator after the oscillator/amplifier to feed the combiner. So you need at least +33dBm from the linear amplifier.
He tried a E280F valve amplifier, but the screening was insufficient using copper clad board on 3.7MHz, and had to stick to a solidstate design, but now it is not satisfying.

Just wonder how they measured above +40dBm? Perhaps you need some specially designed and proven HP ultra low-noise oscillators, which nobody of us ever have heard about?

The circus??? How about *circuses*. With 100W out, an IC-706
ought to cover all the baby monitors in a 100 square mile area.

You didn't even mention base spreading resistance, a major
figure of merit for RF transistors. Newer designers have
considerably lower r-sub-bb-prime than legacy transistors.
Look up the hybrid-pi transistor model. SiGe technology's
claim to fame is low base spreading resistance.

What you say about rbb is true, but SiGe has other 'cool'
characteristics, some derived from low rbb, and some due
to other effects of the 'strained' silicon?... Ignoring
the rbb itself, SiGe tends also to have very low 1/f noise
and good LF noise in general. Also, it tends to have high
Beta (at LF.) So, where an RF transistor might tend to have
a Beta of 20-50, an SiGE part might be 100-300 or higher.

With the combo of the low rbb (and low 1/f noise), along with
the high Beta, the total amount of input current noise and
input voltage noise is damned low.

SiGe would make good oscillators (for less PM noise) and
of course, good preamps. This is one case where GaAs FETS
that are very fast, might be undesirable because of their
worse 1/F noise characteristics.

One big disadvantage of the typical SiGe transistors is
that their breakdown voltage is low. However, the tradeoff
of breakdown voltage is BETTER for a given frequency response
and Beta than a normal Si transistor.

The SiGe transistors are also not very expensive. A part that
works well with reasonably low distortion and reasonably low
noise figure at 600MHz would be significantly less than $1.00.
Unless the transistor is too fast for a given layout, SiGe
can be used at low frequencies (e.g. VHF) while still avoiding
the low frequency noise problems that are common from GaAs FETS
and even other fast BJTs.

> was by Tom, W8JI in 2000.

I just had a look in a couple of references from the
1980s, and the studliest sweep tube mentioned in
the Component Data section of the 1985 ARRL Handbook
is 6MH6, 38.5 watts plate dissipation. Amateur Radio
Techniques (RSGB) mentions 6LF6 (40 watts) and quotes
typical values for tubes like 6HF5 and 6JE6 in ICAS
RF service, both class C and AB1, courtesy Sylvania.

It also mentions that most of these tubes were made
with weird filament voltages for series-string tv
sets. The weird voltage variants are comparatively
plentiful, while the 6.3 volt versions have become
scarce for many types. As a British book it cites
the example of EL509/EL519 (6.3 volt filament), a
scarce tube even then, versus PL509/PL519 (40 volt,
300 mA), readily available.

Reminds me of the black and white Admiral tv set we
had when I was growing up. The horizontal output/damper
tube was a 38HE7. The one that came with the set lasted
years. Once that let go, it ate a replacement every 6
months or so. We finally scrapped it when the picture
tube's emission got too low.

At RF, the base spreading resistance can be large when compared with
the calculated emitter resistance; this makes a serious contribution to
input noise and the NF of the stage.
So the particular version of the model one uses can be rather poor in
determining real-life NF.
BTW, noise measurements at audio frequencies using different collector
currents can be used to determine the transistor's base spreading
resistance.
Once that is known, and the collector current used in the RF amplifier

(for determining Re), one can then calculate noise (or NF) and be rather close to measured values!

Examples of low-cost high-performance (>30GHz at 10mA) SiGe
transistors would be Infineon's BFP620 (82 cents at DigiKey)
http://www.infineon.com/cgi/ecrm.dll/ecrm/scripts/prod_ov.jsp?oid=26182
and Philips' BFU510 and BFU540
http://www.semiconductors.philips.com/pip/BFU510.html
http://www.semiconductors.philips.com/pip/BFU540.html

The Philips transistors look good, but I don't know where to
get them. Mouser stocks a set of CEL's nice SiGe transistors,
http://www.mouser.com/?handler=productsearch._listproductsearch&criteria=SiGe

Sorry guys, I did *mean* to include BSR in series with the B/E
junction resistance, so any reference I made to this junction
resistance should be taken to mean the total of the two together.

> So the particular version of the model one uses can be rather poor in
>determining real-life NF.

NF isn't a consideration in this instance; please ignore it.
And I am well aware of the pi-model. I just want to know if I have it
right that Ebers-Moll will work accurately into UHF provided one
allows for the feedback capacitance and emitter junction capacitance
shunting the input signal around BSR+EBR and thereby reducing the
signal voltage developed across them. Do I have this right?

Thanks,

Paul

Sorry! Corrected above. IOW: whilst the emitter diode resistance is
bypassed at RF by these two capacitances, the base spreading
resistance *isn't* - apart from that, the rest of the post is now
correct, yes? IOW, as the signal frequency increases, the BSR becomes
the dominant component of the device's input impedance... Phew!
Unless of course, someone knows otherwise...

Er, yes, but I'm only interested in the *internal* characteristics of
the device here, so even the bonding wires' inductance isn't an issue.
Thanks for giving me the chance to clarify, though.

A bit of the emitter lead is inside the encapsulation, and a bit is on
the die.

While the IP3 and compression figures may good to comparable devices working in the GHz bands, the huge gain with the low Vce (typically less than 2.3 V) will damage the input IP3 values quite quickly at VHF. This can be a problem in the VHF and lower UHF bands, in which signal levels can be quite high and multiple strong signals may pass the front end selectivity.

For VHF applications, a high current SiGe device operating at impedance levels well below 50 ohms would give good IP3 figures, but apparently the noise figure increases quite rapidly with high collector currents.

Thank you, John, that gives me another chance to re-state the question
more succinctly. I'm not concerned with inductances here at all,
though.
Does the Ebers-Moll equation hold good at UHF+, provided the value one
inserts for Vbe is adjusted to account for the loss of signal voltage
the B/E junction will suffer as much of it (the applied signal
voltage) is shunted around it via the device's internal capacitances?

There! I think I've nailed it this time!

"Noiseless feedback' is very helpful to mitigate the excess amounts
of gain, while pushing the return loss match (the impedance match)
closer to the noise match (the input impedance where the noise is lowest.)
A simple emitter (source) inductor and a little bit of parallel, noisy
feedback can be used to tame some of the interesting UHF+ components.
(The emitter (source) inductor is a case where a small amount of
inductance is much better than too much, because instability can ensue
with too much series feedback (too large an emitter (source) inductor).)

I do agree with your implication that a high current device can be helpful
at low frequencies, but some SiGe components do seem to maintain
reasonable noise performance at high currents.

In any case, the SiGe components do give the GaAs type components a
run for their money. In some cases, the SiGe components are actually
better. The PHEMTs (HP 54143) are also an interesting variation on
the 'fet' theme, which helps to mitigate some of the problems WRT
GaAs. For example, a PHEMT can provide a good noise match at 50ohms,
a transconductance of almost 1MHO at 60ma, and reasonable IP3 (38dBm isn't
impossible.) Feedback can be especially helpful with the high
transconductance FETs.

Has anybody actually used noiseless feedback with these devices at VHF? After all, the fT of these SiGe transistors are in the 30 GHz+ range, so I would guess that the parasitics would mess the situation quite badly, especially when using feedback components.

How critical is the layout compared to for instance MAR-x series MMICs (that are essentially darlingtons) ? Can these SiGe transistors used with dual sided boards and microstrips or do they require multilayer boards and full striplines in order to use feedback ?

>
The simplest case of using an inductor in the emitter (source) lead
is a simple example of noiseless feedback, but adding a noisy
resistor/inductor series pair between the collector (drain) and
base (gate) will help alot also. For example, I have done a design with a
PHEMT (54143), and the source feedback portion along with
normal 'noisy' feedback, the increase in NF was only 0.35dB (starting
from 0.25, yielding 0.60dB.) Even with the increase in NF, it still
performs well. The real-world benefit of using the more common
full noiseless feedback (a transformer scheme) wouldn't really have
significant benefit, except for satellite or super cooled applications.

When I used the term 'noiseless' feedback, I was using the more general
concept that the source inductor would not be very noisy (actually, it
is because of parasitics, but not much.) I have heard that the traditional
'noiseless feedback' where a transformer type scheme would be used HAS
been used at UHF.

Using the trade-off design (using both kinds of feedback concepts), you
can get the 10-15dB of gain, very wide bandwidth, and very low NF. For
IP3, you should get close to the device capability, but the loss in
the normal feedback circuit (along with the suppression devices in
the drain circuit), you'll lose a few dB of P1dB. With the 54143 and
a P1dB of 15dBm (approx) and IP3 of 35dBm (approx), that is fairly
impressive with a real world NF of 0.6dB. An SiGe BJT should be able
to perform similarly (perhaps 0.5-1dB more of NF, and a little less

output power.) The difference is that the SiGe part would be <$1.00,
while the PHEMT would be <$2.00.

The 'darlingtons' will tend to be noisier, but the layout for the SiGe
would be a little worse because of the need for a bona-fide off-chip
impedance match. BTW, take a look at the Sirenza components -- they
are the OEM for some Minicircuits components, and have a wide range
of gainblocks. One 'interesting' example would be the Sirenza 4586,
which has fairly low noise (AFAIR, < 2dB), and also reasonable output
power (10-100mw.) If I was going to avoid the use of super-low noise
components, the Sirenza components are a good second choice. Good
LNA, preamp 'bare' transistors nowadays can work well with 50ohms, and
the high Q problems are not really as troublesome as they once might
have been.

Most of the 'cool', 'new' components like SiGe and PHEMT are really
cool because they TEND to have a good noise match to 50-75ohms, and
also can be pushed to near 10dB return loss without alot of frequency
dependence.

Is there a spice-models somewhere for MMIC's? They give only the
S-parms. One day perhaps I'll get around to abusing a MMIC by not
grounding its "emitter/source" pin, in an oscillator configuration.

Sure wish I had a spice model...

If you have the s-parameters (preferably at more than one frequency) you
can make an equivalent circuit and use that in SPICE. OK for r.r.a.h., I
expect, but maybe not for s.e.d.. (;-)

A SPICE model constructed from s-parameter data can be useful, but only under a very limited set of circumstances. First, it's valid only if the signal level is small. This is often not the case with an oscillator, unless external amplitude limiting is used (as it should be). Also, a circuit very often can oscillate (as well as amplify) at more than one frequency, and a SPICE model that's valid only over a small frequency range won't predict this behavior. (A single frequency SPICE model is simple to construct from s-parameter data, but one covering a wide range of frequencies is just about impossible.)

Some time ago when I was designing a 6 GHz transistor oscillator, I found that the transistor manufacturer's SPICE model didn't produce the published s-parameter data. It turned out that s-parameter data derived from the SPICE model mimicked actual circuit behavior better than the published s-parameter data. Since good microwave s-parameter measurements should be easier to make than SPICE model extraction, this shouldn't have happened. My guess is that the manufacturer's s-parameter test fixture or calibration routine had a flaw they weren't aware of.

I'm very surprised that it's not easy to find SPICE models for the more common MMICs.

It MIGHT be educational to model the darlington MMIC by using a darlington configuration of some UHF transistors. Perhaps, use a low current transistor in the first position and a higher current transistor in the output position? Perhaps the first transistor running at 5-15ma and the second one running at 30-40ma, circuit designed for 2-3volts? The low voltage would give a wider choice for transistors, but you might want to juice up the Vce to 4-5 volts for wider swing. 12ma for the first transistor would give a fairly good (generally) noise match to 50ohms (assuming some examples of 10-50GHz ft), and the higher current would give significant output capability. (AFAIR, the 5-20ma range sometimes provides a good noise match to coax impedance levels. For lower current, there is a possibility that the need for transformation will cause enough input loss that it might be better to throw away a little NF for higher Ic.)

For SiGE, you might just use the same components -- the transistors have generally better noise behavior and tuning the circuit with different geometry transistors might be a little less useful. I haven't tried one yet, but the Infineon BFP640 looks interesting. For NORMAL transistors, the BFR340 and BFR360 look interesting (they aren't so hot, but they still have good VHF/UHF noise characteristics. They don't have as much of the LF SiGe behavior, however.)

Make sure that the collectors are connected together, and it might be helpful to use a series R-L for the first emitter load. You'll find that the circuit is alot better behaved when feedback is needed rather than letting the first collector be at AC ground. (If the first collector is placed at AC ground, the gain will be higher, but the circuit will be potentially more difficult to tame.)

After modeling the circuit with vendor supplied nonlinear spice models, then it would be interesting to compare the behavior with existant MMICs.

John

wrote (in <10g0gjq7mhb96dd@corp.supernews.com>) about 'The bi-polar
transistor at RF', on Thu, 22 Jul 2004:

>(A single frequency SPICE model is
>simple to construct from s-parameter data, but one covering a wide range
>of frequencies is just about impossible.)

Yes. If you have s-parameter data for more than one frequency you can
see how the derived Spice models vary with frequency. You can add bits
to a 'master' model to improve the match with the single-frequency
models until you run out of patience. (;-)

What's the problem in making up your own (accurate) wideband Spice
model from measurements you make yourself on a VNA?
I'm also under the impression that a parameter such as (for example)
the base-collector capacitance lifted from a manufacturer's data sheet
and inserted into Spice won't work accurately. Why is this?

The problem is in figuring out what components to use, and how to connect them, to imitate the (usually complex) way the s-parameter data change with frequency. If the circuit is very simple, with one or two components dominating the frequency response, it's quite possible. But an MMIC isn't likely to be in that category. Grab some s-parameters from an MMIC data sheet and give it a try, and you'll see what I mean. Then, for a real eye-opener, dust off your VNA, make your own measurements, and see how close they come to the manufacturer's.

> I'm also under the impression that a parameter such as (for example)
> the base-collector capacitance lifted from a manufacturer's data sheet
> and inserted into Spice won't work accurately. Why is this?

Depends on the accuracy you're looking for and the range of operation. A simple transistor model, such as one made from data sheet parameters, will work surprisingly well for many purposes. But it's a linear model, good only for a very limited range of operating conditions. In a real transistor, Ccb (for example) varies strongly with Vcb. A complete SPICE model accounts for this, along with several tens of other factors ignored by simpler models. If you're operating the transistor with a small signal and at voltages, currents, and frequency near those on the data sheet, a simple data sheet model can often be good enough.

One of my most treasured texts is _Modeling The Bipolar Transistor_, by Ian Getreu, published by Tektronix in 1976 (Tek P/N 062-2841-00). It's long out of print, but it might show up on eBay or elsewhere from time to time and I highly recommend it to anyone seriously interested in transistor modeling.

Thanks, Roy. It's a pity Kevin (for whom I apologise) lacks the depth
of knowledge that so many advanced "build-it-yourself" radio amateurs
have acquired over many years of hands-on experimentation.
I'll certainly try to get hold of a copy of this book. It sounds just
the ticket for my purposes.
Your reply throws up another interesting question: which model
parameters are essential for adequate modeling of the BJT up into UHF,
and which, by their omission, call the model's reliability at beyond
such high frequencies into question?
Thanks,

p.

<< I have an 422 keyer/paddle combo and had to cut the cable that goes from the keyer to the rig. >>

Greg-

I'm confused too!

Am I correct that the paddle has two contacts that each get pushed against a ground contact? That is what I would expect, so the stereo plug would be needed for the paddle. The two contacts would connect to the tip and ring, and ground would connect to the stereo plug's shell.

If your rig has a built-in keyer, you could plug this paddle into it and it should work. This assumes the stereo plug is the same size the rig uses, or you have the necessary stereo adapter. The only problem might be having dot and dash terminals swapped.

The output of your external keyer is two wire, comparable to the output of a straight key. It wouldn't need a stereo plug, but if you use one with the ring not connected you can avoid a nuisance problem when plugged into a rig that has a built-in keyer.

You could use an RCA "Phono" connector for the output of a keyer. I've seen these used on a QRP rig, but never on a Kenwood or Icom. I think Radio Shack sells adapters if your rig needs one.

Oh dear...Clueless as usual again my son.

History....

I had my first electronics kit at 11. At that age I discovered on my own how to feed a signal into a transistor radio and us it as a pre amp for my guitar, playing it into an old valve radio gramme. By the time I was 14/15 I was constructing the electronics for my home build disco deck units which I used to take to school. During ages 17-21 I was actively building and designing much guitar equipment such as phaser pedals, guitar amplifiers, wah-wahs and distortion boxes etc. During my time at university I earned reasonable cash doing repairs for a local music shop. This knowledge allowed my first pro designed power amp to still out perform most, if not all current commercial pro audio power amps today, in areas such as distortion, e.g. http://www.studiomaster.com/hp5.html. Following on from this is 20+ years solid professional post graduate design in areas such as the ultrasound medical imaging equipment front end boards, fibre optics, telecomm equipment, telemetry, etc. Simply put, I have more practical

experience on electronics than you have had hot dinners.

The knowledge that you present of electronics makes it quite clearl that your "experience" is aimless soldering of components. As usual, your pissing in the wind.

Sorry, perhaps I didn't explain properly. I'm talking about *Spice*
parameters here and there are a finite number of them. Obviously Cje
and Cjb are essential for accurately modelling into RF., but are there
any others that must be included (excepting of course factors external
to the transistor like lead-length and case/ground capacitance etc.)?

Looking for a Power Supply for a Henry 4-K amp (5cx1500 tube model). If you have one and are looking for a new home for it send info to both email addresses below.I am looking for a complete floor cabinet unit or at least on that can be brought back to life for my R.F. deck I found at Dayton this year. Thanks in advance for any help, 73' de aa8wl Sam

Yes, it must be truly awful having to put up with grubby oiks like me
who keep asking stoopid questions about basic electricity that a child
of 6 would know the answer to.

>I have knowledge and experience gained over many years. I am good at

Well day centers aren't really my thing. I don't need the company of a
bunch of old fogies like Jim Thompson to stimulate me. I read
extensively - something you yourself might benefit from. When was the
last time you actually picked up a book?

>Indeed I do. If one doesn't vote for oneself, how does one expect to get

What is the reason behind the two scales on the Heath QM-1 dial scale
for the resonating capacitor? One scale is for Ce (effective C)
and the other is for Ca (actual capacitance)? The manual
does not give a clear explanation of the two scales. Does this
relate to stray capacitance measurements in the coil?

Guess this one "stumped the band". The reason, as related to me on another group, is due to Heath's using a 5000-pF cap. to provide a low-impedance injection point for the coil, vs. the resistive element used in most Boontons. This cap is effectively in series with the tuning capacitor, thus two scales are needed: one for series and one for parallel resonances.

The smaller scale is for reading used to give values you can use in a
formula to calculate self-capacitance of the coil

Heathkit chose to use a 5000pf capacitor, while I would not use it, in
fact the QM-1 is modified, and the different approach is shown on
http://home.online.no/~la8ak/m1.htm , and believe mine is better

I understood what you meant, but you didn't understand my answer, so I'll be less subtle and more blunt. The components you need for accuracy depend on what the application is, and how much accuracy you need. A single component -- a dependent source -- is adequate for a lot of uses. Two components (a dependent source and one capacitor) are adequate for a lot more; all the tens of SPICE model parameters still aren't enough for some others. You either have to have a basic understanding of what you're doing in order to determine (or make an educated guess at) which parameters are necessary for the application at hand, or you've got to toss them all in and hope they'll be enough. There's no magic list you can use to look up which ones you need and which you don't.

Hello everybody,
I wonder if anyone has already tried to receive the signal of NDB beacons ?
These are long-range radio beacons, used by aircrafts for navigation,
operating in the frequencies from stg like 200 to 500 KHz I think. Their
signal is AM-modulated with a sound signal of their code (three letters) in
morse.

It would be an interesting project to build a receiver and ADF for these
beacons, but I'd like to know if anyone has already tried that.

Thanks for your answers ;-)

Some AM radios for the Swiss market go up to 285 kHz on the LF band.
Some beacons can be heard. You can modify an MF radio to receive 250 to
420+ kHz, but you can't get too close to the IF, which may be 450, 455,
459, 468 (+ n x 9 kHz) .... kHz.

Rather than struggling to stabilize an analog oscillator at UHF, you might look at some of the synthesizer chips intended for cell phone use. TI has same gigahertz synthesizers (2050,51,and 52 I think) that could be divided down with a prescaler. With the prescaler you would end up with a square wave, but for a LO that's probably a better deal anyway. They also have some single chip "transmitters" (TRF4400, 4900) which are essentially synthesizers with a little more output. These parts are less than five bucks at DigiKey. Analog Devices also has some nice synthesizer chips up into the UHF range. AD parts are pretty hard to buy, but they are very good about sampling.

True about the sampling, but note that you can buy many Analog Devices
PLL and DDS parts from DigiKey now
(http://dkc3.digikey.com/PDF/T042/0351.pdf). This is a fairly recent
development.

If we could only convince DigiKey to distribute Mini-Circuits parts, it
would be a true one-stop shopping experience.

The receivers are dead simple. You have so much atmospheric noise that
it's hard to make the receiver noisy enough to matter. Antennas are
usually amplified capacitive probes for omnidirectional, or the
traditional loop for RDF.

I read in sci.electronics.design that Tim Wescott
<tim@wescottnospamdesign.com> wrote (in <10gaofq3iuq6q25@corp.supernews.
com>) about 'Receive NDB beacons ?', on Mon, 26 Jul 2004:

>I never knew about the 450 + n x 9 business -- do you know why that is
>so?

European LF and MF transmitters have been on 9 kHz channel spacing since
soon after WW2, but in the 1970s (IIRC) the frequencies were made
multiples of 9 kHz, which is why the Droitwich transmitter changed
from 200 kHz to 198 kHz. At that time, we (the European setmakers)
studied whether to standardize the IF at a multiple of 9 kHz or an odd
multiple of 4.5 kHz. It was found that whistles, due to various high-
order effects in receivers, were minimised if the IF was a multiple of 9
kHz.

The next step was to look at *which* multiple of 9 kHz minimised image
interference problems between LF and MF transmitters (France had three
LF transmitters at that time and UK and a number of other countries had
one each). It was found that 450 kHz was the best value, but many
setmakers had used, and some continued to use, 459 kHz and other
frequencies.

One other advantage of 450 kHz was that miniature IF transformers made
in the Far East for 455 kHz for the US market could be tuned down to 450
kHz, maybe with a few tens of pF of added capacitance, whereas they
would not tune up to 459 kHz.

455 kHz is particularly bad for UK, because of the BBC transmitter on
909 kHz. It is subject to (theoretically) 1 kHz beat note interference
with the second harmonic of the IF, radiated into the antenna from the
detector circuit.

Tim,
Let me take a wild guess that makes sense. You want the local oscillator frequency to be a multiple of 9 KHz (The EU channel spacing) to make it simpler to design the PLL. Seems that 450 would work with both 9 and 10 KHz spacing.

Are they still using the NDB stations? seems kind of redundant with VOR, that has been around for 50 years or so.

Yes. Do a web search for 'LOWFER' and you'll find a *lot* of interesting things.

Briefly: My Sony 2010 multiband receiver tunes down that low, but reception is poor. It's much better if I use a longwire antenna _and an antenna matcher_ (inductor and capacitor) to tune to the desired frequency. I can get ZBB (Bimini, Bahamas) from my home in Athens, Georgia.

Longwave radios from Europe will tune part of this band; it's used for broadcasting over there.

Sometimes the good old stuff is the best. That's why I still use hemp
and paste on pipe threads and not all this new-fangled stuff that start
to leak the next morning. And my trusty ol' shortwave receiver brings me
the world whenever I want to. It never told me "host connection has
timed out".

> "Ratings are for transistors .... tubes have guidelines"

Tubes in a nicely designed amp sport a dynamic range from here to the
Klondike :-). Some newer FETs can do that as well but there is no
romantic glow in them.

Others have already provided an excellent range of answers, so I
just had to jump in with a nitpick. :-) I speak both as a former pilot
and as a long-time hamateur.

The phrase "NDB Beacons" is redundant. 'NDB' in this context means
'Non-Directional Beacon,' so the correct presentation of the term would
have been "NDB's" or "ND Beacons."

Perhaps its a beacon transmitting information about NDBs - hence an NDB beacon.

But thats not important right now, if you're going to be picky then NDB's is reference to something pertaining to the NDB eg the NDB's code generator had a loose chain.

I remember working on one (20yrs ago) where it was is a full height 19" rack and the bottom unit was indeed a motor with 'sophisticated' cam and chain system where you programmed the actual code to be transmitted by adjusting the stators/rotors. I've not seen one since - I guess its the size of a shoebox now?

73's intentionally mistyped :)

I based my conclusion on:

1) FEMA uses LF as a backup and
2) My local 50KW FM powerhouse went from S-30 to S-3 during this latest
sunspot. Whaty will happen to a <100 watt VOR?

I have heard over 800 NDBs in 30 states and 26 foreign countries from my location in central North Carolina over the years. I have used the stock Icom IC-71A and Sony 2010 radios and usually long wire antennas. I have done dxpeditions to the coast of NC and a pinnacle (2000 ft. tall rock, Pilot Mountain) in western NC which has added some new ones in the log from time to time. My expereince with NDBs goes back to the late 60's with a US Navy WWII long wave radio which was a lot of fun but a real "hoss" of a radio. Through the old Prodigy computer system before the wide use of internet I met a hobbyist i California and had a good time comparing notes on what we were both hearing. I hav found over the years that the best time to listen is in the Fall of the year, just before dawn, when the weather begins to change rapidly with the onset of frosts. Of course you must be able to copy CW (Morse code) and that's a lost art. The internet has been a great resource for identifying NDBs and there are several sites with a lot of good information. You might try www.airnav.com. The Lowdown was a useful publication of the pre-internet day and back copies would be an asset to anyone with an interst in NDBs. As an amateur radio operator I have worked over 300 countries and spend most of my time on amateur satellites now but the hunt for a new NDB ranks right up there with some of the best time I have ever spent with the hobby. This has been one of the more interesting strings on this group in some time and it sure would be nice to keep it going with others posting their experiences. pcox

Some time ago it was some request for bilateral amplifiers, perhaps it should have been mentioned that it is also such things as bilateral mixers, see RA3AAE type bilateral harmonic mixer on http://home.online.no/~la8ak/c21.htm

It has been described some good and some wrong ways to make this mixer, but the original info from RA3AAE is clear enough to understand I have used this sort of mixer for simple projects on frequencies between 3.5-144MHz, and it works with simple diodes as 1N4148 for low noise figure as only 7dB (provided it is correctly terminated)

I forgot to mention that I already have some LMX2306 PLL-chips, and the idea was to use one of them together with the oscillator. The oscillator must therefore be voltage controlled with a varicap.
Is the only possibility to make a low-frequency oscillator and multiplicate it up, or is it possible to make a more-or-less stable VCO running directly at 420 MHz?
And should I if necessary make the low-frequency oscillator down in the HF region with several multiplication stages, or is it stable enough to have it in the VHF region followed by only one tripler stage? Any thoughts?

Are you a radio ham?

It seems that you want to use 10.7MHz IF for your receiver project,
but it is too low, 21.4 would have been a better choice, while I
believe NOKIA used 70MHz for some of the NMT systems, and 21.4MHz as
second for a reason I don't know

Greetings

I am looking for information on toroidal cores...

I grew up in electronics and amateur radio during the 60's and 70's. Now I am retired and need more information concerning toroidal cores....

I have a bunch of cores and would like to know how they compare with open form coils etc.

Is there a website that teaches you about toroidal cores. How to identify them how to calculate how much wire to wrap for a partical inductance value. Etc...

> believe NOKIA used 70MHz for some of the NMT systems, and 21.4MHz as
> second for a reason I don't know

I have already made one receiver for the 2m band by having a VCO connected to
a SA612 to get a 10,7MHz IF, followed by a SA615 to get a 455KHz IF.
For a few days ago I found out that I wanted to receive the 70cm band too (430-440MHz), and therefore just removed some turns from the coil in the VCO, and put a
3,3pf capacitor in series with the trimm cap. (a desperate action!) To my disappointment that stopped the whole oscillation, and I therefore understood that it was not the correct way to make a UHF oscillator.
I knew that it was possible to multplicate a low frequency and then get a high frequency, but this subject was some cryptically to me, and therefore searched for help here.

What I want to know now is how it is recommend that the VCO is built up. How many multiplication steps?, and how these multiplication steps should be designed?
Shortly spoken: What is the best solution when making it analog together with a LMX2306?

The plan is to use the same configuration as with the 2m receiver: SA612 - 10.7MHzIF - SA615 - 455KHzIF - Sound. Will the image frequency slip through too easy with a 10.7 IF. I do not demand perfection yet.... I just want it to work. So, I can put in a 21.4MHz IF later, if it becomes necessary. Now, I only have 10.7MHz filters, and want to go for that.

I am sorry for bad explanation, but I hope you understand some of it!

Thank you

Ruben

Now that people say "ATM machine" we should abbreviate it "ATMM."

Then they can say "ATMM machine"...

The LMX2306 should be a good choice. If you don't feel like building
your own VCO, you can always get one from Mini-Circuits for $15-$25 that
will cover the range you need.

I don't think it's a good idea to try to homebrew a VCO for this range
unless you have access to a spectrum analyzer to characterize its noise
performance. Building a decent VCO is one of those 'educational'
endeavors that's full of surprises. You will want to choose a PLL loop
bandwidth based on the VCO's noise profile, and that can be tough if you
can't see what you're doing.

With a Mini-Circuits VCO, you can just plug the specs into the EasyPLL
simulator on National's site. That may take some of the fun out of it,
but it all depends on where you want to spend your R&D time.

Ruben ... by way of explanation ...

Generally, you would like your received frequency, your local oscillator, and your IF about equally spaced because this makes filtering easy. In practice, we gravitate to a few common IF frequencies because we can get parts for them. But, if any pair from those three ends up "close", we have trouble. In your case, you want a 430 MHz LO to generate a 10 MHz IF from a 440 MHz signal. 430 is terribly close to 440 so it's not such a good plan. It's tough to get tight filtering at high frequencies, and at best, you will hear 420 almost as well as 440, if you can hear 440 at all over the racket of the LO.

VCOs are tough to get stable, even at HF. It's pretty reasonable at 2 MHz, hard at 10 MHz, and almost impossible at 100 MHz. Multiplying isn't much of an answer, either, because you multiply the drift, too. Now, presumably you are building an FM receiver, and that at least gives you a little breathing space. The wide bandwidth and FM capture effect make it a lot more forgiving than, say, CW. But building an analog oscillator for those frequencies that is stable is really hard.

When amateurs first started heavily using 2 meters, the LO was either a crystal, which you switched to change frequencies, or a synthesizer that mixed signals from a collection of crystal oscillators. That gave a nice, stable signal. Crystal oscillators are notoriously stable, and are very useable even when multiplied 8 or 12 times. More recently, Direct Digital Synthesis has become the norm in VHF and UHF gear. With DDS, a processor is driven by a very high frequency crystal oscillator. The processor then reads a sine wave table and outputs to a digital to analog converter. This creates a stepped sine wave, but if the oscillator is a lot higher in frequency than the synthesizer's output, the approximation is pretty good. Further, if the oscillator's frequency isn't harmonically related to the output frequency, it can be quite easy to filter, resulting in a very good sine wave, with crystal stability. However, in the case of a local oscillator for a 612, you don't really need a sine wave, in many ways, a square wave is better. That's why doing something like a gigahertz synthesizer stepped down through a prescaler is a possibliity.

As you have already found out at 2 meters, building an analog oscillator at high frequencies takes a lot of fiddling around. The higher in frequency you go, the more fiddling around. Worse, as you get much above 2 meters,

circuit layout and construction techniques play a huge part, as the stray capacitance between components become at least as large as the intended capacitances in your tuned ciruits. Lead inductances also become significant. This is probably why you couldn't make your modified oscillator work - there are L's and C's all over that you can't see!

The first time you do it, DDS is no cake walk, either. There are inexpensive chips that do the whole job for you, but there is a whole new learning curve. These chips need a control word loaded into them, and job one is understanding how you get from the frequency you want to that control word. Typically the control word is loaded serially, which means that your design probably has to include some sort of microprocessor to calculate what to load and then serialize it. So while the circuitry is very simple and non-critical, the whole thought process is different and, although it is dirt simple once you've done it the first time, that first time is sort of a bear.

So it does look like you have a number of design decisions. You will need a different first IF, perhaps using your 10.7 as a second IF. Heck, maybe you choose 146 as the first IF, and use your existing 2 meter model as the IF strip. Next, are you going to spend a bunch of time on stabilizing the LO -- even if it's 300 MHz it's still no easy task -- or will you choose another path, maybe mixing crystals or a DDS. One real possibility is to build a VCO at some reasonable frequency and mix it with a crystal oscillator to get up around 300 MHz. And although DDS is very simple the second time, the task of learning how to do it will probably take as much time as stabilizing that analog VFO, although you will save a bunch of time on the NEXT project.

Lots to decide ... I hope this helps a little

..

Of course, before channelized operation on VHF came along, the solution
for stable operation was a converter ahead of an existing converter.
An RF stage, the mixer, and a crystal controlled oscillator. The
receiver was tuneable, while the much higher in frequency oscillator
in the converter was crystal controlled. Pick the right frequency for
the output of the converter, and it helped with image rejection issues.
And of course, it was simpler to build separate converters for eachof
the bands than build a whole receiver for each single band.

After all, it seems that he wish to build a receiver - not a converter
- to cover 433-438MHz band, possibly somewhat lower for listening to
FM signals. The use of MiniCircuit VCO is a good idea, and it might be
stable enough to listening without the PLL, while it is somewhat
troublesome to tune. So he could build the PLL after having the
receiver going.

But I would recommend another first IF with a roofing filter, it may
not need to be very selective, perhaps a simple 45MHz bandpassfilter

Since the FM segment is somewhat lower here than elsewhere it
simplifies the construction, and he need not receive any local traffic
from the other side of the Atlantic ocean. Believe repeater input in
Germany is 430-431MHz, but perhaps not so interesting to listen to the
few times in a year you could hear some stations

Any BC453 receivers left in those junk boxes? I have a BC1206 that
hasn't been converted, if anybody really wants it we can haggle.
(covers 200-400khz, runs off 28vdc all loktal tubes with 28v on the
plates!).

You can try putting padder caps in parallel with the tunning cap in
an AA5 and re-align it to cover part of the 200-400khz band. I
tried that once and was able to pick up a close by NDB. Hint:
go down to the airport pilot shop and pick up a sectional chart. The
NDB's are listed on the chart, where they are located and their call
signs and frequencies. This will give you an idea what you can pick up.

Yes, but I haven't heard of any new ones recently. They were relatively cheap to install (at least the ground equipment), but now new installations go toward GPS approaches which require no ground equipment and are more accurate. Still, the old NDB approaches work and are common especially at smaller airports.

For sale, PICKUP ONLY, a large! collection of vacuum tubes. NOS, used, not so used,
from 0A2 >> 117Z, 1000 maybe 2000, don't know for sure but a lot. Most are in boxes and alphabetically arranged in about a dozen, cut down Xerox paper boxes. Total weight maybe 200 pounds. I am keeping the "high value" stuff for now (12AX7, 6L6xx, 1L6, sweep tubes) those ebay-able types are not included. I am asking $300 for the whole lot. I'll try to take some pictures and post them this weekend.
Conditions of sale:
1) You must pick up, I will NOT ship and you must take them all. We are moving and I don't want to move them again.
2) Cash only.

I am located just south of Detroit Michigan, in Allen Park.

Hello!

Thank you all of you for the valuable help you have given me!

I became some curious about these DDS-circuits. I have read something about the AD9835. That one can generate sinewaves up to 50MHz, but it seems like you write that some DDS circuits can make much higher frequencies. Is that right?.. or do you just have to multiplicate those frequencies from below 50MHz up to the frequencies you want? Can you give me some examples of recommended DDS-circuits that are capable of making UHF frequencies?

Thank you

Ruben

1205. Stability of huff & puff.

Gosh, I don't even know if it's possible to adequately tune the oscillator
from 2.00 - 2.50 Mhz using a variable
capacitor, when the bandwidth of the Rx is only 20Hz. I'd need a good slow
motion drive I think. I have an Eddystone 898 dial.

The DDS produces useful signals up to about 1/4 to 1/3 of the clock rate (theoretically up to 1/2, but filtering gets difficult). ADI makes DDS's with a 300MHz clock rate.

You would want to mix the DDS output with a crystal-generated reference, and take the sum or difference as your LO.

I've just started an interest in NDB DXing.

There is a good list you can join.

Go to:

http://www.beaconworld.org.uk/info.htm

Download the welome pack and then open up the FAQ. That tells you how to
join the list.

I've got a circuit for a NDB RX if you want to look at it. It's in PDF
format.

Other links I found.

Do you mean spurs? Possibly. The popular DDS from Analog Devices
clocks at 50MHz, so you can easily get 15MHz energy out of it. Divide
that by 6 and you'll get more spectral purity and your 2.5MHz high end.

You can also make a very low phase noise VCO that runs at 2MHz and
stabilize it's frequency with a DDS. QEX has had articles on this.

Once locked, it's as good as the crystal controlling it. Might move 5-20 Hz
however to the nearest lock point.

> make much higher frequencies. Is that right?

TI has a couple of parts worth looking at. They are a little more involved to deploy than the Analog Devices parts, but they go mugh higher in frequency.

The TRF2050 is a 1.2 GHz synthesizer:
http://www.datasheetarchive.com/cgi-bin/q.php?pi=76585

The TRF2052 is practically the same part for 2 GHz. Gigahertz prescalers are pretty inexpensive, so it would be a simple matter to divide one of these down to what you need.

The TRF4400 is a 440 MHz "transmitter". Basically, it is a DDS, FSK modulator and amplifier on a chip:
http://focus.ti.com/prod/folders/print/trf4400.html

This part looks a little simpler to use than the 205x. The 4900 is the same thing for 900 MHz. Although the part is aimed at 433 MHz, Steve "Melt Solder" Weber has used it down to 50 MHz. The TI parts are significantly less expensive than the AD parts. (But AD has a great sampling policy!)

The AD985x are probably the easiest to use. Keep in mind that you have essentially a crystal oscillator, although tuneable. Even with, say, a 9850 at 30 MHz or so, multiplying it up for your injection isn't all that bad since you have a lot of stability to begin with. There must be a hundred plans out there for 9850 based VFOs. The 9854 is a quadrature DDS ... you might get cute with the quadrature outputs to get some multiplication.

All of these parts are TSSOP parts, so a printed circuit card is a must. FAR circuits has some protoboards that you could use, and for the 9850, NJQRP has a little board that contains just the basics for making the 9850 play. A number of other places have protoboards, but these two seem to be about the cheapest. There is a good possibility that someone on that side of the pond is cheaper for you.

Mmm, are you saying that a stabilized oscillator will drift up to say + or -
20Hz, or that when tuning it will tend to jump in 20Hz steps? I think
that's what you are meaning, and that once locked the drift is much
less than 20Hz. Similar to xtal stability. I'm just wondering what a
frequency counter would read when tuning:

2,000,000 Hz jumps to > 2,000,020Hz jumps to > 2,000,040 Hz etc?

And I wonder what the stability would be once tuned. I guess crystal specs
ought to give a ppm figure.

> I am looking for information on toroidal cores...

Other posters have pointed you to websites and programs with the calculations. By the way, the Radio Amateur's Handbook, of course, also has good information.

A few 50,000 foot comments that were overlooked....

Toroids come in powdered iron and ferrite. Powdered iron results in lower loss and lower inductance and is generally used in tuned circuits. Ferrite is used in chokes and broadband transformers.

Both loss and temperature coefficient tend to be poorer in toroids than in air wound inductors. However, they are much smaller, and the magnetic field doesn't extend out the way it does for a helical inductor, so parts placement is less critical. They are also less prone to microphonics.

For amateur HF use, -2 and -6 powdered iron is generally used for tuned circuits, except for VFO's where -7 is popular due to its lower temperature coefficient. -43 and -61 ferrites seem to be the most popular for RF transformers.

Powdered iron is colored to tell you the mix. HOWEVER, and this is a biggie, the colors amateurs use are the colors that Amidon uses for it's AMATEUR RADIO targeted line. Other manufacturers and even the same manufacturer for a different market may use different colors. The most popular are red (-2) for <10 MHz, yellow (-6) for >10 MHz, and white (-7) for VFOs. If you buy surplus toroids the colors may lie so measure before you believe. You can't tell ferrites apart by looking at them.

The digits before the dash are the size, in hundreths of an inch. So for example, a T50-6 is a half-inch powdered iron, mix #6 while an FT37-43 is a mix #43, 3/8" ferrite. The microhenries per turn does change a bit with the core diameter, but generally the size is selected simply to be able to fit the number of turns needed on the core.

hope this helps

Greetings

I am now looking for information on analog to digital converters. I am looking for information on how they work....

Reason: I need one that can converter from about .1 volts, if possible, to about 15 to 20 volts. Thats about a 15 volts one end to the other....

I have one that goes from, I believe, the traditional 0 to 5 volts, I assume...

I would like to see how d/a converters work and how I can get one to extend it's range....

I think, actually, I need to know more about d/a converters so I can ask more intelegent questions....I know what I want it to do, now I just have to find out how to make one do it...

Larry ve3fxq
p.s. sorry for being sooo wordy...

The Huff n Puff has discrete frequencies that it will lock a VFO to. In most designs, those frequencies are somewhere between 5 and 30 Hz apart and when your VFO is tuned and stopped, the HnP will then pull it to the nearest lock frequency and lock the frequency (NOT the Phase!) there.

It will then keep the VFO at that frequency, dependent on the drift rate and direction of the crystal used for the divider. BIG advantage is that it does not appreciably raise the phase noise level of the VFO as does a PLL, BIG disadvantage for your purposes is that it is not continuously tuneable. If you played the math, you could make those lock frequencies come out where you wanted them, but since it's a percentage thing, only over a relatively small span of frequencies.

Initially you are talking about A/Ds, but later you talk about D/As. I
assume that that's just a typo and your talking about A/Ds in all cases.

Well most of the A/D converters that I have delt with cover a range of
0 to 1 volt or -1 to +1 volts. But, I have worked with some that offer
a 10 volt input range.

As far as converting your input range, I would just use an op-amp as
a level translator to take your 0 to 20 volt range and convert it to
the input spec of the A/D. Add another one in front, for buffering,
and possibly another to handle any inversions.

If you want to have a little fun you can use a couple of op-amps,
some counter chips, and a D/A (no typo) to make a nice tracking A/D.

But you are right, you need to learn a lot more about A/Ds. What kind
of resolution do you need? What frequencies are we dealing with?
And many more questions.

If your are dealing with some slow signals then you can use some
pretty cheap op-amps and A/Ds. But higher frequency conversions
would require more sophisticated parts.

Probably if you do a search on digital processing techniques you
will come across a tutorial or two on the conversion processes.

The absolute best book I have ever seen on how electronics works, how to
design good circuits and not design bad circuits is called "The Art of
Electronics" by Horowitz and Hill.

This book has everything you would want to know about A/D converters
and DACs, and a whole lot more.

It is full of practical circuit information.

Look at the data sheets for the DAC0801 and similar parts. They will
show you how to use an opamp as a current-to-voltage converter to obtain
any voltage range you need.

You don't necessarily need a multiplier with a DDS. These parts are fabricated in processes with an fT of many gigahertz, so their unfiltered output spectrum is almost like what you'd expect from a comb generator. So, for a narrow frequency range, you can use "images" from a low-frequency DDS.

To do this, you replace the low-pass filter usually used at the DDS output with a bandpass filter that covers the desired range of output frequencies. Then, you tune the DDS so that one of its DAC-alias harmonics falls where you want it.

Example: You want to generate signals between 420-425 MHz. You have an AD9850 DDS clocked at 100 MHz. If you tune the AD9850 to (for example) 20 MHz, its output will consist of a comb of signals at 20, 120, 220, 320, 420, ... MHz (Nfc+fo) and 80, 180, 280, 380, 480, ... MHz (Nfc-fo). Normally you'd use a low-pass filter with a cutoff around 50 MHz to eliminate the higher-frequency aliases, but in this case, you actually want to use a bandpass filter to pass the alias frequencies between 420-425 MHz (4fc+fo) and reject the adjacent ones at 4fc-fo (375-380 MHz) and 5fc-fo (475-480 MHz).

The AD9850 data sheet (search for it at www.analog.com) has a nice summary of this effect.

There are two main drawbacks: (1) Any spurs from the DDS will be at least 20*log(N) times worse at the alias frequency than at the fundamental, where N is the clock harmonic number you're using; and (2)

you may also have to contend with harmonics of the 20 MHz output signal in this example. The latter probably won't be too bad around 400 MHz, but the former might be.

If I were doing this, I would probably use a cleaner DDS like the AD9852/9854 or one of the new AD9950-series parts, but that may not be necessary in your case.

I have forsale 2 crystal filters;

1) yf-88 1.8 kc crystal filter for the Kenwood 820 series radio and
any other that uses a 8830 khz i.f. this filter is made by Seiwa Corp.
and sold by the fox tango who is now international radio. asking $60 shipped
u.s.

2) Fl-250 250 hz crystal filter for the Drake R4-c series of receiver.
it has center freq. of 5695 khz and was originally sold by Drake radio in
the late 70,s
and manuf. by Network Sciences. asking $75 shipped u.s.

>

I have a large collection of Huff Puff stabiliser articles reproduced with permission on my website, see http://www.hanssummers.com/radio/huffpuff/contents.htm, and also links to my own version of the stabiliser http://www.hanssummers.com/radio/huffpuff/fast/index.htm and all the other Huff Puff stabilisers on the internet that I am aware of.

Frequency stability depends on your crystal, you could use an oven controlled reference for ultimate stability.

Distance between lock points depends on your design parameters. Yes, when you tune you'd see 2,000,000 -> 2,000,020 -> 2,000,040 for example (once the thing had settled down, which should be very fast but again depends on your design parameters).

Another factor is the frequency deviation around the lock points. By nature, the Huff Puff stabiliser works by applying correction pulses to the VFO, to marginally increase or decrease the frequency to move it closer to the lock point. There is therefore a small variation in frequency. Again the amount of Huffing and Puffing depends on your design parameters.

In general if you start off with a good oscillator, then you can design your Huff Puff stabiliser to only apply small correction pulses, which will enable you to obtain minimal deviation about the lock point. This also allows you to design for closer together lock points, without risk of the VFO jumping to adjacent lock points.

In any case it is best to reduce the effect of your stabiliser on the VFO to the point at which it comfortably stabilises, but no more - otherwise it will be difficult to tune. The stabiliser is always fighting against your efforts to tune the VFO. You want to be able to tune a small shift slowly without the stabiliser being so vigourous that it cancels out your attempt.

Definitely go for Peter Lawton G7IXH's "fast" stabiliser design involving a shift register to delay the comparison pulses. The
CMOS 4517 IC is a 128-stage shift register which is perfect for this purpose. One way to think of this design compared to the original stabiliser

design is as 128 ordinary stabilisers all Huffing and Puffing in parallel. The overall effect is much better frequency control and less deviation around the lock points. I prefer to think of it as a means of statistically averaging many binary pulses into a more analogue correction signal. If you use the "fast" design your end results will be superior in terms of minimal frequency variations relative to the lock point.

In my 80/40m HF receiver (http://www.hanssummers.com/radio/polyphase/index.htm) I am using a 14MHz VFO Huff Puff stabilised at about 44 Hz (if I recall) lock points. This is divided by 4 to produce 3.5MHz quadrature for the Tayloe mixer (direct conversion followed by polyphase method unwanted sideband cancellation). The lock points at 3.5MHz are 11Hz apart. Frequency deviation is unnoticeable (sub 1Hz). See the VFO & stabiliser: http://www.hanssummers.com/radio/huffpuff/fast/index.htm.

In conclusion I'd say you have no problems with 20Hz IF bandwidth and a decent Huff Puff stabilised oscillator.

Thank you for taking the time to read this.

Your Freedoms are in jeopardy! RadioShack Corporation has filed an injunction in a Texas Court that has shut down an opinion website, http://www.radioshacksucks.com, in direct violation of the Freedoms of Speech, Expression and Peaceful Assembly, as guaranteed to us by the Constitution of the United States. If other companies learn of this, they will use it against any website that speaks out against that company. This is extremely dangerous, as it will change the face and scope of the Internet.

If Big Business continues to dominate our lifestyles, we will lose our freedom to worship as we see fit. We will lose our freedom to vote for the candidate that we think will do the better job. We will lose our freedom of the press to accurately report on current events. We will lose everything we have fought and died for in the past 228 years Do not tell this to the descendants of those that have bravely fought in previous battles and wars, for their ancestors would have died in vain. The Constitution will have been overruled by Big Business.

RadioShack is on a vicious witch hunt and will not stop until they dominate our lives. RadioShack must be stopped now, before it gets any later or any worse.

Here is what you can do to help: copy this letter and add your signature to the bottom. Mail it to the following people:

Leonard H Roberts
CEO RadioShack Corporation
100 Throckmorton Plaza
Ft Worth, TX 76102

The Honorable Kenneth Curry
401 W BELKNAP

Thanks.

One question: For a 2.00 - 2.50 Mhz oscillator, what, do you think, using huff & puff, would be the minimum tuning jump you could acheive? Could you acheive a 5hz jump or less? Rich.

It is a very short range, I must say. Something down to -100 would
have been nice. And what of the 50Khz resolution? I hope that's at the
very top end!

Hello to all...

I recently found some very pleasant software I thought might be of interest to many on this list.

It's called HamCalc and is available as freeware. This is NOT the faboulous collection of programs from George Murphy, VE3ERP, but different software from England.

You can check it out at:
http://www.vwlowen.demon.co.uk/radio/files.htm

This software doesn't do anything that you couldn't accomplish with a calculator, but it is very nicely packaged and is easy to use.

For those who write all of their own software, DO NOT go to this site!! And please do not criticize me for having the good sense to recognize and take advantage of the efforts of others who are delighted to share their work.

> huff & puff, would be the minimum tuning jump you could acheive? Could
you
> acheive a 5hz jump or less? Rich.

I would think < 5Hz would be easily achievable. My divided-down 14MHz VFO has 11Hz lock points at 3.5 - 4MHz and it isn't even a particularly fine oscillator to start with (just the single-transistor internal oscillator of the 74HC4060).

The actual minimum distance between lock points that you can achieve depends on how you design the stabiliser, which will depend on how stable your oscillator is to start with and how capable your Huff Puff circuit is at stabilising it. The latter depends partially on the design (i.e. use the "fast" method and 128 or 256 shift register stages), and partly on the integrator time constant and how much "pulling" range you allow (e.g. the size of each Huff or Puff).

When you play with Huff Puff stabilisers you will quickly find that the optimum design is a tradeoff between all these factors. The Huff Puff stabiliser will give best performance when it is stabilising an already-good oscillator. So it's best to do as good as you can with the VFO design, then add the stabiliser. I am planning to build a Huff Puff stabilised crystal oscillator at some point, for my QRSS experiments http://www.hanssummers.com/radio/qrss/index.htm. There, the distance between lock points can easily be sub 1Hz.

Hi, all concerned:

I'm asking advice on replacing the motley stuff I have now, so I can build the N2PK VNA, and maybe a K2 later on. I do need surface-mount capability -- I can still see the lil duckpluckers ;o)

Compressed air is available for venturi-type devices.

Used/new sources are fine; low cost, while a consideration, is not all there is to it. A good tech is worth good tools, right?

TIA -- 73, Dave, N3HE

Metcal makes the best equipment. It's expensive, but often available on
eBay. The older STSS units take all the current MX-500 accessories, and are
the best value. I've got two of them.

You do not have to spend much money to get surface mount capability.
Used / surplus units from Pace, Weller, Haako, MetCal have been hitting the
market
(e,g. hamfests, eBay) as repair centers and closed down; production moved
off-shore and firms close door.

There are a few homemade systems (and the toaster oven reflow approach that
works well)

MetCal uses an RF heating approach, these tips/heaters (new) are expensive
for occasional use.
Weller's new WSL system is made in Germany and uses their "L" series tips.

I still use the Weller TCP series for much of my soldering (including some
surface mount),
even though I have a full Pace MBT 250 sitting right next to it.

So far, I've built two N2PK VNA's and have built many other boards (all
successful) with 0.025 pin spaced components. Only components are a 1 mil
tip on an Antex iron, 0.015 silver bearing solder from Radio Shack and a
headband magnifier. Oh, you also MUST have a wad of de-soldering braid.

A minority view is that it would be possible and interesting to attempt a stable VCO first LO frequency.
The oscillator needs a stable resonator and one option is a section of rigid coax with shorted end or as a delay element (0 phase one wavelength) .
The level can be high to allow high level mixing, a varicap padded out to give just enough pulling can be considered as a phase shift element.
Employ a good buffer between the lo and the mixer.
Remember to terminate with attenuation pads to minimise reflections.
and a 70MHz first IF makes life easier, there are some useful SAW filters at 70 MHz

Hi guys,

I see in Chris Bowick's book on RF circuit design, he provides 8 quite long-winded formulas for converting between S and Y parameters and vice-versa. I'm always prone to making careless errors (particularly with signs) with these kind of equations, so I was wondering if there's a simpler, graphical method for conversion using the Smith Chart. After all, that's what it was devised for - the elimination of computational errors in such calculations.
I've tried using the vastly simpler rectangular/polar co-ordinate conversion formulas, but they don't plot correctly on the Smith Chart, it seems.
So, does anyone know of a simple graphical way to do it on the SC?

Thanks,

p.

You don't need anything exotic for most surface-mount work. Like Harold
says, solder-wick is your friend. It lets you solder the fine-pitch
parts in place without worrying about bridges.

A Metcal iron is nice (I use one myself) but not really that much better
than a Weller iron costing 25% as much.

Or, for that matter, the old "huff and puff" technique could be used to frequency-lock a UHF VCO to the nearest kHz. The VCO would need good phase noise but not long-term stability, making the coax resonator idea practical.

Paul

I used to think I could do alot of things with Smith Charts and Z theta
Charts. I'm way out of practice, but might be able (and willing) to point
you to where you can solve the problem you now have.

Since I am not smart enough to see *exactly* whats involved with S and Y
in your post, I may be off base with this. -- Are you aware that the
admittance of an impedance can be identified by overlaying a transparent
Smith Chart over another Smith Chart with "zero" impedance overlaid on
"infinite" impedance.

Jerry

Jim

I'm kinda embarressed to admit that I'm not even sure what Y and S refers to. I do remember that impedances plotted on a Smith Chart will follow the lines of constant "conductance" on the transparent overlay. Maybe thats too fundamental for inclusion in this thread. But, it sure is a quick way of predicting how much shunt Xl or Xc is needed to "tune" to a more desireable impedance.

Jerry

Yup and you can get one with the admittance chart already overlaid
on the impedance chart. any point plotted can be read either way and
the s-params are also directly read from either with dividers or a
ruler.

I have no clue why Paul is converting between rectangular and polar
and replotting. The point should stay put.

Indeed. And that is something I've considered. But The way Bowick
explains it, it *ought* to be possible to perform the conversion
summarily by a simple graphical method. Unfortunately, the
arithmetical method he describes only works for linear polar charts,
which of course the SC certainly isn't linear!
And the guy who suggested the 180' rotation: I reckon that's *part* of
the solution, but simply doing this alone merely converts impedances
to admittances. S-params are typically denoted in the form x+/-yj
whereas the Y-params are denoted as vector and angular co-ordinates,
so further mappings and/or translations are required following any
rotation...
Still, I'm sure someone out there will know. :-/

Paul

I realize that I dont understand what needs to be done. I'm just too far
out of touch with technology. But, is there any chance that a Ztheta Chart
overlay would be of any assistance?? Properly used, the combination of
Smith and Ztheta can be a usefull tool. That overlay provides the impedance
magnitude with its angle, at a glance, for all R+/- j X.

Jerry, I appreciate your tip. But that's not actually what I'm trying
to ascertain. The complete SC is hard enough to read as it is without
overlaying a spherical grid on it! Your idea might well work, don't
get me wrong, but I just need to know if S-Y mappings can be carried
out with the Smith Chart *alone.*

Thanks,

Paul

Semiconductor s-params are usually listed as magnitude and angle, with
the mag sometimes in pure scalar form, or sometimes in dB. A universal
conversion program would be nice, espacially if it included equivalent
reactance, capacitance, inductance, stuff like that.

I sense some confusion about s and y parameters. S parameters aren't impedances -- they're dimensionless transmission or reflection coefficients. They do have a real and imaginary part (or magnitude and angle) like an impedance, but that's as far as the similarity goes. You can overlay a Smith chart on a polar plot of reflection coefficient (e.g., s11) and directly read the normalized impedance which causes that reflection coefficient. But what you read from the Smith chart isn't the the reflection coefficient -- that is, it's not the s parameter. When you reverse the Smith chart, you get the admittance causing the reflection coefficient, but this still isn't a y parameter. If you invert an s parameter, you still have a dimensionless number.

Y (admittance) parameters are a different critter, are measured differently than s parameters, and have the dimensions of admittance. Transformation from s to y or vice-versa isn't simple. For example,

y11 = {[(1 - s11)(1 + s22) + s12s21] / [(1 + s11)(1 + s22) - s12s21]}/Z0

(See, for example, Gonzalez, _Microwave Transistor Amplifiers, Analysis and Design_.) From this you can see that in order to find y11, you not only have to know s11, but also s12, s21, and s22. So it's simply not possible to convert from y11 to s11 if s11 is all you know.

I used a micro to count the freq to 10Hz resolution instead of a shift register. The micro drives the LCD freq display, but also calculates any drift by comparing the current count to the "locked" count. It would output a pulse which was integrated by a loop filter/voltage follower. I am not sure about the math involved but in practice the loop behaved like a PLL and would oscillate with 10-20 Hz variations or wander about with some loop filter combinations, particularly if there was no damping in the loop. If you counted to 1 Hz resolution, then I presume you could get 1 Hz resolution in the loop. In practice this means counting over a long period (1 sec) and I suspect short term variations in the VFO freq (jumps or phase noise) could could the loop to lose lock or behave strangely, so the quality of the oscillator would be the limiting factor. It might be worth looking at one of the old HP sig gen circuits (eg 8640B) I think they used the "huff and puff" scheme to stabilize the oscillator.

Bullshit. it's magnitude and angle. You plot Z = R + jX on the
friggin chart and measure the distance from the origin to get
magnitude. You measure the angle to get.. angle. Imagine that.

If you do mag = sqrt(R^2 + X^2) and angle = atan(X/R) and plot it,
you'll see that no conversion was necessary at all.

Roy,

Thanks for another well informed and sensible reply.

Paul,

Why limit yourself to going from S to Y parameters. Might as well go for H and Z parameters too.

If possible, find yourself a copy of HP Application Note 154, April, 1972 "S-Parameter Design". In the first few paragraphs they point out that H, Y, and Z parameters are defined by voltages and currents.

Quoting:

"The important thing to note here is that both open and short circuits are essential for making these measurements.

Moving to higher and higher frequencies, some problems arise:
1. Equipment is not readily available to measure total voltage and total current at the ports of the network.
2. Short and open circuits are difficult to achieve over a broad band of frequencies.
3. Active devices, such as transistors and tunnel diodes, very often will not be short or open circuit stable."

So, since the 60's, RF designers have been using S-parameters to characterize devices and circuits. They are based on reflection and transmission in a 50 ohm system. They are measurable. Why do you feel you want to use Y parameters? (Why-oh Y-oh?)

>S-params are typically
>denoted in the form x+/-yj whereas the Y-params are denoted as vector
>and angular co-ordinates, so further mappings and/or translations are
>required following any rotation...

I don't know which way you want to convert, but the conversion from
magnitude and angle to complex Cartesian co-ordinates is:

x = mag*cos(angle), y = mag*sin(angle)

Be careful of the signs of sin and cos if angle is negative. sin is
negative and cos is positive. You can see this if you draw a simple
diagram of x and y axes.

To convert the other way,

mag = sqrt(x^2 + y^2), angle =arctan(y/x).

This isn't difficult mathematics in these days of scientific
calculators, but you do need to be careful about signs, AND check that
the result is credible: if it isn't, you probably made a keying error.

For example, when you calculate angle, then calculate its sin and cos,
to check with the original data.

Hear! Hear! Thank God there are still some folks here who know what
they're talking about.

[snip]
>So, since the 60's, RF designers have been using S-parameters to
>characterize devices and circuits. They are based on reflection and
>transmission in a 50 ohm system. They are measurable. Why do you feel
>you want to use Y parameters? (Why-oh Y-oh?)

I agree entirely, Rex. I'd much sooner use scattering parameters alone
for the reasons given in your post. The only flY in the ointment is
that some datasheets only provide Y-params and when those times arise
one needs to be able to convert between the two. Now it transpires
from what Roy has stated that there is no feasible way to convert the
two using the Smith Chart. That's fine; at least I know I'm not doing
all that mathematical manipulation unnecessarily. John L's suggestion
of writing a routine to do the fiddly bits now seems the most likely
solution. Should only take about a line-and-a-half of C++.
Thanks, both.

2004:
> I just now learned about S and Y parameters. I learned that they are
>WAY too complex for me to understand. I think it *is* time for me to
>apologize for commenting when I could have been more help by remaining
>silent.

I suspect that in fact they aren't too complex for you to understand.
There are lots of over-complicated explanations around. The Y
(admittance) parameters relate the input and output currents to the
input and output voltages, using the basic equation (Ohm's Law V = IR
inverted) I = VY.

Because there is internal feedback and feed-forward inside the
transistor, the output voltage has an (unwanted, usually) effect on the
input current and the input voltage has a wanted effect on the output
current. For this we get two not very difficult equations:

Iin = VinYin + VoutYfeedback

Iout = Vin Yfeedforward + VoutYout

The suffixes are often replaced by two numbers, where 1 means input and
2 means output.

I in = I1, Vin = V1, Iout = I2, Vout = V2.

Yin = Y11, Yfeedback = Y12, Yfeedforward = Y21, Yout = Y22.

S parameters deal with how well the input and output impedances match a
specified characteristic impedance, usually 50 ohms, and are based on
incident and reflected powers.

In the general case, the possibility appears to be allowed of applying
power at the output as well as, or instead of, the input. Normally, of
course, this isn't the case; the 'output power' flows out of the device
and is what you want!

Pina is the power applied to the input and Pinr is the power reflected
(if the input impedance doesn't match the chosen characteristic
impedance). Pouta is the power produced (or applied) at the output and
Poutr is the reflected power at the output (if there is a mismatch).

Using the numbers 1 and 2 as explained above:

Pinr = S11Pina + S12Pouta

Poutr = S21Pina + S22Pouta

Again, these are not very difficult. However, some of the calculations using them can be a bit more complicated, but don't use any mathematical concepts more advanced that square roots, sin, cos and tan, and x + jy.

There is a paper in Electronics, October 16 1967, 'Quick amplifier design with scattering parameters' by William H Froehner (then of TI), which gives a lot of useful information, and a reference to a previous, simpler paper. I only have a monochrome photocopy, and some of the diagrams use colour, but it may be possible to retrieve the original through a library service.

It might be nice, but it's dumbing down the subject, and anyone using s-
parameters for real had better *understand* what he/she is doing,
otherwise any success would be a pure fluke.

I read in sci.electronics.design that Roy Lewallen <w7el@eznec.com>
wrote (in <10glmf6regc7re4@corp.supernews.com>) about 'S - Y Parameter
conversion with Smith Chart', on Fri, 30 Jul 2004:

>Transformation from s to y or vice-versa isn't simple. For example,
>
>y11 = {[(1 - s11)(1 + s22) + s12s21] / [(1 + s11)(1 + s22) - s12s21]}/Z0

It doesn't look too simple written in ASCII, but it only uses addition,
subtraction, multiplication and division, with brackets [1]. It's a bit
easier to understand if you get rid of the double division by moving Z0
up-front, and write out the remaining division as a fraction:

$$y11 = Z0 * \frac{(1 - s11)*(1 + s22) + s12*s21}{(1 + s11)*(1 + s22) - s12*s21}$$

[1] OK, you need a few basics of phasor arithmetic:

If S is a phasor = magS,angleS and T is a phasor = magT, angleT, then:

S + T = (magS + magT),(angleS + angleT)

S - T = (magS - magT),(angleS - angleT)

S*T = (magS*magT),(angleS + angleT)

S/T = (magS/magT),(angleS - angleT)

To convert dBmagS in dB to magS as a number, magS = 10^(dBmagS/10). (/10
because the equations are about power, not voltage or current.

> clearly.

I understand that you don't understand that you can read Y, Z, and S
params directly off the chart. The only time you need the
conversions is if you don't have a vhart.

here's your OP:

"I see in Chris Bowick's book on RF circuit design, he provides 8
quite
long-winded formulas for converting between S and Y parameters and
vice-versa. I'm always prone to making careless errors (particularly
with signs) with these kind of equations, so I was wondering if
there's a simpler, graphical method for conversion using the Smith
Chart. After all, that's what it was devised for - the elimination
of
computational errors in such calculations.
I've tried using the vastly simpler rectangular/polar co-ordinate
conversion formulas, but they don't plot correctly on the Smith
Chart,
it seems.
So, does anyone know of a simple graphical way to do it on the SC?"

So turn to page 106 and notice that an S param is plotted and if the
light and your eyes are good enough, you'll see that the point is
also labeled 2 + j1.5

Now what's with the learning disability?

> If you don't have anything useful to contribute to the

Motorola also has a couple ANs on "amplifier" "design" and
"impedance matching". Keywords would be those quoted above and
"Linvill".

Well so? Since you think you know better than everyone else here,
perhaps you'd like to tell us how to convert this S-parameter, plotted
on the chart as you say as 2+j1.5 to its Y-parameter equivalent
without using the conversion formulas shown on P.107? For the
avoidance of doubt: show us how you would derive the equivalent
Y-parameter for 2+j1.5 by the use of the Chart alone.

>I just did. Twice. Don't jump my ass just because what you heard is

So you replied before I could add to my last post, but...

> Since you think you know better than everyone else here,

I haven't contradicted anything that was said other than that which
you've said and no one has bothered to correct me on anything. Are
you also delusional? I should however take the opportunity to point
out that John Woodgate also mentioned that polar conversion, but he
did mention that it was for cartesian coords, which doesn't apply
to your current quandry.

notice that you alluded to using polar/rect conversions? That works
for finding going between admittance (mag, angle) and
conductance/suseptance. My head was still in the cartesian plane but
I can see why it didn't work for you.

BTW, I think if the data sheet gives Y params, I'd use 'em unless I
had another reason to convert to S-Params.

> perhaps you'd like to tell us how to convert this S-parameter, plotted
> on the chart as you say as 2+j1.5

2 + j1.5 is not an S-param it's a Y-param

> to its Y-parameter equivalent

You mean its reflection coefficient. Its magnitude is the length of
the line and its angle is, again, the angle. No conversion
necessary, it's a graphical solution. That's what you wanted and
that's what you got.

> without using the conversion formulas shown on P.107?

Did I say I could? ... Aside from my initial knee jerk polar/rect
conversion.

Those eqs look like the were derived from eqs for circles.

> For the
> avoidance of doubt: show us how you would derive the equivalent

No, only that one post and I had to use the term because you've had
enough time to memorize that book word for word and yet you insist
on confusing basic things with statements like:

"S-params are typically denoted in the form x+/-yj whereas the
Y-params are denoted as vector and angular co-ordinates"

Also, the post started with the abrev, "VB", not "bullshit".

>

Well, at least you'll have attached *some* value to it. Do you think
I can use it to reduce the Miller capacitance seen at the base?
Hmmm... "cap", "charge", and "input" in 2 lines. Sounds like an
electronics discussion. I thought you said that wasn't allowed here
in sed.

That's the pot calling the kettle black. Aside from the need for
others to repeatedly spell things out for you, you're also the guy
who braged about the record setting flame war you had with some
dude. I don't suppose yuo consider that a waste of bandwidth. Don't
add hypocrisy to your transgressionsl.

> by just simply stating "no it's not possible to perform a summary
> translation between S and Y parameters by mappings on the Smith Chart"

But for the third time, it is. The eqs are for getting a *numerical*
answer. If you have the chart, you just read the conversion off of
it directly. Start with the example on pg 105.

That's three (or so) times I've told you and yet you can't
understand why people tire of your lack of understanding.

> and we could all have got on with our lives.

Didn't know you had one ;) ... couldn't resist.

> dragging out the discussion yet adding nothing to it

Ok. You're right. I added nothing. It was all bs. You *can't* do it
on the SC and you *must* use the conversion formulas. Happy now?
Bowick and I are both wrong.

I enjoy reading this group, mostly for short sweet questions with short sweet answers. I take the time to sort through all of the questions and all of the responses in a thread because if I can't offer some advice, then maybe I'll learn something. In this case, I feel my time is wasted by both of you because there's nothing I can offer to this purely emotional exchange, and nothing I can learn from what's being offered. I think the majority of the readers probably feel the same.

Can you guys take this to a more private venue please??

In anticipation of making a bug key up from bits
of brass and old clock springs, what form does the
damper take?

I've never played with nor handled a bug key, and my
question arises from having seen the the vibroplex site.

Just because s-params are in mag <ang format and not in a + jb . At
least I've never seen tham that way. Furthermore, I know exactly
what PB is referring to, in case you didn't notice the page number
refs.

Yeah. I'm on hold here, so I haven't left yet. Delays.

You know nothing whatsoever of the nature of that thread and my input
to it. On that particular forum, my input was instrumental in
assisting an innocent person to defend his hard-won real-world
reputation against malicious allegations made over the Internet. It
cost the transgressor half a million pounds in damages, thanks in no
small part to my guidance and support in an area of expertise in which
I *do* unquestionably excell. I'm not here to dish out advice, I'm
here to try to learn something about a subject I'm not fully
conversant with.

>> by just simply stating "no it's not possible to perform a summary
>> translation between S and Y parameters by mappings on the Smith Chart"

For at least the *fourth* time, it isn't!

>The eqs are for getting a *numerical*
>answer. If you have the chart, you just read the conversion off of
>it directly. Start with the example on pg 105.

Nope. The example on p.105 is nothing to do with converting between S
and Y parameters; it simply demonstrates a graphical method for
expressing a normalised load impedance in the form x +/-jy as a
reflection coefficient in terms of a magnitude and angle; that's all.

And as John W said, how do you tell whether the point referred to on the Chart is actually a Y-parameter at all??

>That's three (or so) times I've told you and yet you can't
>understand why people tire of your lack of understanding.

Some people have a gift for expressing themselves lucidly. Roy's single, concise posting was an example of that craft. You have demonstrated nothing of that calibre.

>> and we could all have got on with our lives.
>
>Didn't know you had one ;) ... couldn't resist.

I do, but it's x years minus 1 day thanks to your obfuscation.

>Ok. You're right. I added nothing. It was all bs. You *can't* do it
>on the SC and you *must* use the conversion formulas. Happy now?
>Bowick and I are both wrong.

I didn't say Bowick was wrong. I never said that Bowick stated it was possible to make the conversion solely by means of the graph. You, OTOH, still say that.

I asked purely for information. It might have been that there are limits
on the values that the various parameters can take, and that example was
outside the limits for an s-parameter.

>Furthermore, I know exactly what PB
>is referring to, in case you didn't notice the page number refs.

I noticed that, but I, and doubtless many others, don't have the book.

Hi,

On this subject of Bug Keys.
I still use a old J36 I purchased in 1957 for 30 bob.
It was made for the US Navy in 1942.
By the Lionel Model Train Company, under license from Vibroplex.
I also have quite a few components from another scrapped J36.
If anyone has parts missing from there old J36 I might be able to
help them out.
But only to genuine homes.

If you intend to make one.
Get a copy of The Story of The Key.
By Louise Ramsey Moreau W3WRE.
It was a Morsum Magnificant Publication.
Its a wonderful history.
And lots of photos to get ideas from.

de Johnny G3LIV.

Is the purpose to damp the oscillator when the operating
lever returns to the central position?

With the brass ring, presumably being loose, it is lifted slightly
by the returning-to-zero oscillator?

The Smith Chart has served its purpose.

It was a much-simplified version of earlier, more complicated charts, dating back to the Victorian age used to solve electrical engineering problems involving complex hyperbolic functions.

It applied ONLY to the HF spectrum, serious calculating errors occurr if applied to the LF spectrum and below although few engineers realised this. And still don't.

But it became popular with design engineers immediately following its introduction in the late 1930's when HF broadcasting, TV and Radar, and relatively short, low-loss HF transmission lines became the vogue.

The design and use of HF and VHF lines was much further accelerated during WW2 when all the principal participating nations indulged in vitally-urgent, secret work associated with VHF communications and Radar. The Smith Chart became available just at the right time. It could almost be considered as a war weapon used by all sides.

But it became reduntant just as rapidly on the invention of the scientific pocket calculator. In particular calculators which had hyperbolic functions. The pocket calculator could now, much more easily, with equal facility, undertake transmission line calculations involving the whole of the frequency spectrum from DC upwards.

It is said that, these days, the Smith Chart has eductional value. It allows problems to be visualised. Indeed it does. But there are other just as good educational methods which involve mathematical procedures.

My first association with transmission lines was in 1944/5. I have never used a Smith chart in the whole of my career. Neither have I ever met anyone who has. Perhaps I haven't met many people.

The Smith Chart, as sentimental and as nostalgic as it may be, is redundant.

Reg.

Could you please explain that a bit more? The chart is a graphical way
of doing mathematics. Where does frequency enter the picture?

If you mean that the characteristic impedances of 'transmission lines'
at low frequencies aren't resistive, I quite agree.

I have a copy of a article originally published by Brian Murphy,
VE2AGO in QST Magazine (date unknown). It is an article on how
to properly adjust a semi-automatic key, or bug. It gives you a
lot of insight into what all the adjustments are for and and
nice overhead drawing of an automatic key.

If you do make one you are going to have to adjust it anyway.
If you like, I can send you the files via email. There is only two
files, one html and one gif. Or, I can probably post it somewhere on
the net. Let me know. The email in the sig works.

What's the cutoff frequency below which a Smith Chart won't work?

There is a good electronics shop in my town, so I have no need to
visit RS.

My running joke has been that if I am bored, I can go into RS and ask
technical questions.

The current economic downturn has meant that a lot of high-tech
professionals have ended up working at a RS until the economy
recovers, so the joke is less true currently.

Happy trails,
Gary (net.yogi.bear)

Major employers, especially those with government contracts, require
pre-employment drug testing these days. Maybe that's why few engineers
think Smith charts somehow become invalid below a certain frequency.
Your mileage, obviously, has varied. :-P

Perhaps Reg can also tell us in which year since the Chart's inception
the mathematical relationship between a graphical solution to a
computation and a numerical one broke down?

I've never experimented myself, but have seen varicaps made of aluminum foil and glass, where the adjustment was made by sliding the foil/glass leaves back and forth. Looked like it would work very well.

All graphs are redundant and can be replaced by equations or tables.
However, a picture (graph) is still worth a thousand words (or numbers).
A glance at a graph tells me more than an hour of studying endless rows
and columns of numbers.

==========

It has never broken down. It's the engineers' educational system which has broken down. Mathematics gradually became a neglected subject. And that began around 1945. Students and professors were war casualties. Present products of the system are mentally handicapped. They are reduced to using look-up tables and manufacturers' digital-chip catalogues with little understanding of what's really going on in the world.

It suffices after a fashion but is very poor engineering economics and a squandering of the Earth's limited resources.

Which is a long way from S-Parameters.

Reg.

This question shows a limited understanding of the LF, and below, frequency spectrum. There are an infinite number of octaves.

What is the cut-off frequency of a simple R+C high-pass filter?

It is first necessary to specify how many decibels the response must have fallen.

Reg

I think you are wrong about Smith Charts being limited to use at low
frequencies. Maybe you can take time to tell me where my thinking has gone
wrong. I'm not really a good engineer. I avoided the mathematical aspects
of design whenever possible.
I considered the Smith Chart a plot of *all* impedances with + R values.
That means that there is a point on the Chart that represents every
impedance independent of the frequency associated with that impedance
determination.

I have maybe been in error when I state that I can look at an impedance
plotted on the Smith Chart and identify which combination of the minimum
number of reactors will be best for matching that impedance to the
impedance of your choice, at any frequency. I realize that there are
conditions where my method gets difficult, but, I contend that a Smith Chart
is a nifty tool for those of us who arent smart enough to do the math.

Jerry

Damn Reg. So far, I'm really liking what you're writing, history
included. As much as I like shortcuts, they never satisfy my desire
to truly understand an engineering concept which can only be related
(IME and to my satisfaction, etc) via mathematical analysis. If you
tell me that a range of resistor values will light up an LED
supplied with a certain range of voltage, I'm not going to sleep
easily until I know why. Yeah, there are some neat analogies, but
that doesn't yield an ohmic value. Math will.

That's why I'm ranting. Running to Wendy's might be a quick fix, but
it isn't my way and neither is randomly shoving values into Spice as
great of a tool as it is. It's just a tool and it's no better than
the operator.

I should stop now because PB already told me to keep my views to myself if they don't answer the question. I should be plonked post haste.

There are other considerations in detemining how to arrange the matching net. Once you have the topology, the chart is pretty convenient, IMO. And it doesn't save you from any *complicated* math. Obviously, going from j5 to j0 is simple arithemtic - you need -j5 reactance or suseptance depending on whether your selected topology calls for a series or shunt.

The nice thing IMO is that you can keep track of each step on a graph of the transformation and not have to look at a blur of calculations.

IMO, it avoids no arithmetic at all. You still have to add and subtract. And with or without it, you have to convert the reactances to puFFs and Henries for that freq.

If all you're interested in is the straighforward conversion from S to Y and Y to S, you might have a look at the free download program 'Vierpol' from RFglobalnet. Google should find the URL of the download site.

I have convinced myself that the Smith Chart alows it to be determned if
it is preferable to add series (+ or - X), or Shunt (+ or - X) depending
where the complex Z plots on the Chart.
I really admire the guys who can match impedances with math only. I just
dont have good study habits, so I'm not smart.

Ok. I think I understand your confusion, now, and I hope I didn't
call it a Y param (part of the OP subject) and just said it's not an
s-param, which as I said, isn't expressed as a complex number, IME.

The example is given as a load of Z = 100 + j75 which normalized to
50 Ohms is 2 + j1.5 and as I've tirelessly tried to drive home can
clearly be read off the chart as 0.54 <29.7 deg

Due to the geometry of the SC, a normal polar/rect (v.v.) conversion
doesn't work and as I mentioned earlier, those conversion formulas
look very much like something that came from the circle equation. If
you have a conversion chart handy, look at the (1-y), (1+y) factors
and consider the fact that the origin is at 1,1. It's obvious to me
that the formulas were derived analytically from

(x-h)^2 + (y-k)^2 = r^2

with h, k = (1,1), i.e., the center of the s-param circle is at the intersection of the unit R and X circles.

Interesting that the +/- signs in the conversion are kin to the hyperbola (no?), which IIRC Reg mentioned (xmission line eqs), but I'll wager it all came from the SC's circular geometry, mainly because I coded an SC chart and went as far as calculating the intersection points where the arc change line width and eventually terminate like a real printed SC, not the typical CAD couple of lines that go to oo . You could say that I have deep carnal knowledge of the chart's construction. My app displays the Z, Y, S params of the cursor position in the status bar and damned if I remember whether I naively (or brainfartedly) used polar/rect conversions for that.

> Wot's a VNA ?

Vector network analyzer. Since the mid-1970s, maybe earlier, they've
been able to generate both scalar and polar plots of S-parameters
directly. Very handy for antenna work, if you don't mind dragging 75
pounds of gear around! I just wrote some code to grab Smith-chart plots
off a friend's Advantest R3762AH, and I'm going through some real
hardware envy right now.

> I have to agree there are certain aspects, a few octaves of my education,

True; this thread has been generating more heat than light since it
began. I've stayed out of it since I'm not a certified guru at this
stuff. I don't want to post any incorrect or incomplete information
that will further confuse our esteemed interlocutor. It'd probably be a
good idea for all others who aren't fully up to date on the principles
to do the same. :)

Conversely, I've already hit 'print' twice on J. Woodgate's posts to
keep them around for posterity....

The LF data signals are DGPS (Differential GPS) signals. Google dgps,
lots of civil engineering/survey folks use it. In conjuction with a
regular gps receiver it makes for incredibly accurate measurements.

>Reaactance depends on it. I must not understand your question.

Reg wrote that the Smith Chart doesn't work at low frequencies. Since
it's just a way of solving equations, it can't fail to work. What
'fails' is that at low frequencies, either different equations apply
(no) or different terms in the equations become significant (yes).
>>>
>>> If you mean that the characteristic impedances of 'transmission lines'
>>> at low frequencies aren't resistive, I quite agree.
>>> --
>> ================================
>>
>> The characteristic impedances of ALL practical lines aren't resistive.

Well, yes, but at high enough frequencies, the reactive term is small.

Zo^2 = (R + jwL)/(G + jwC)

For high enough w (omega), provided R (series resistance) and G (shunt
loss resistance) are low, Zo^2 = L/C.

> But
>> your statement just about sums up the situation.

You agree with my explanation above, that it's not the chart that
'fails', but that terms in the equations change significance at low
frequencies?

There is nothing whatsoever the matter with the chart. It does no more and no less than what it is intended for.

There is everything the matter with the user - begining with a lack of education!

If you can find one in decent working or rebuildable shape, look for
a BC-314 (12 vdc) or BC-344 (120 vac) receiver. It tunes from 150kc to
1500kc,and is the best darned AMBC/NDB receiver I've ever had, will even
dig out stuff my R-390 and Super Pro can't hear, plus it goes down lower
in freq. Used one from the 70's through the mid-80's then foolishly gave
it away, just recently found another. The BC-1206 is not a bad little
RX, but is a very "simple" set, even compared to the BC-453.

What type of conversion were you going to do on the 1206? I remember
solid-stating one years ago. I have the stock schematic if anyone needs
it BTW. Email me direct, not with the email shown on the top of the
post, though. Actual email address can be found on QRZ.com under NU4G.

The Non Directional Beacon thread got me to thinking about this
very inexpensive kit I just built. $12 each, 2 for $22.75, shipped.

http://home.att.net/~jacksonharbor/lfconv.htm

Simple to assemble kit, works well, though I had to add
a few more poles of LPF in front of it to get the AM broadcast
out. The guy gives you your choice of crystals for whatever
band you want to upconvert to. Manual for the board is on
the site. I highly recommend this, especially for folks just
starting out exploring LF and VLF - this upconverts from a bit
above 10 KHz to 500 Khz. Surprisingly enough, there is still
lots of signals to hear down there. Go to lwca.org for more
information and links to VLF and LF info.

Is it possible that this method of which I have no knowledge could
determine that you need to do this

```
|
C| RFC
C|
C|
|
| || ||
+----||---+-----||--
| || | ||
| C|
|/ C|
-| C|
|> |

when you really need an LP pi for harmonic suppression? Please
elaborate. Sounds like an excellent contribution waiting to happen
to those who are teachable.

> I really admire the guys who can match impedances with math only. I just
> dont have good study habits, so I'm not smart.

Eh? It's not math. It's arithemetic. Give yourself more credit.

Match 50 + j25 to 50 + j0 .... ok you need -j25 which is a series
cap that suppressed no harmonics or a practical shunt inductor that
does. Assume I'm assuming the application I'm assuming ;)

How do you infer the correct topology from the chart only?

MMike

I havent learned to type either.

I wrote a short article in Electronic Design magazine in 1966 wherin I outlined a simple way of predicting which combinations of series and shunt reactances would be most appropriate for matching any given impedance. I'd have to re-read it to learn what I wrote. I sure couldnt give any advice about using a Smith Chart from "the top of my head". I've been away from engineering since 1969 when I was layed off from TRW.
The basic thought elaborated on in the article was -- divide the Chart into 8 sections, chosen to identify what combination of reactances are most suited for producing a match. I think that anyone who worked for a short time with impedance matching would find the article unnecessary.
The article included some information on how a Z theta chart can be usefull in analyzing how transmission line transformers effect impedances.
I have forgotten everything I ever knew about Z theta Charts.

> A glance at a graph tells me more than an hour of studying endless rows
> and columns of numbers.
> --
==========

Depending on our particular educational history, we all have our separate preferred ways of studying technical situations. And we all usually come to the same correct conclusions.

I too become exhausted by studying endless rows and columns of mere numbers.

Graphs are indeed very useful. But I often find that the form of a mathematical equation provides just as deep an insight into what is really going on in the practical world. Praps I am fortunate at being equally adept at both analytical forms. It must have begun during my school days.

The advantage of equations over graphs is that they are nearer to the quantitative than they are to the qualitative world. They are more precise. And in engineering it is numbers which, ultimately, matter most.

If you look in Radcom Sept-2000 to Jan-2001 under the article
"PicATUne", you will find an interesting series of articles about
building an 150W ?? auto ATU with home constructed capacitors.
They used Freezer bag plastic (specific type mentioned)dielectric,
some form of grease (to exclude air) and brass shim for values from
18pf to over 1000pf.
I guess the aluminium foil would be just as good, if not better, if
you can make a good electrical connection to it.

wrote (in <1qqjyblf14xnh$.dlg@news.individual.net>) about 'S - Y
Parameter conversion with Smith Chart', on Sun, 1 Aug 2004:

>How do you infer the correct topology from the chart only?

You can't. But then the chart doesn't act as a typewriter or Turkish
bath, either. The chart will give you both T and pi solutions. You make
the choice between them on other grounds, such as harmonic suppression.

Many thanks for posting the link. same here all these 'calculators' get one thinking!
It doesn't, however, mention RG-8?
I wanted to compare the difference, at around 160 mHz (marine VHF), between retaining existing RG-58 or replacing with RG-8, for the approx 40 feet from top of our sail boat mast to the VHF transceiver. So I used RG-213? instead.
Difference about 1 dB. Or approx 20%. probably not really worth while?
Terry.

Usually when I see someone bitching about Radio Shack it's from one of
the small brained no-lifers who get their kicks from going to Radio Shack
and trying to show off how much more technically intelligent they are than
the clerks behind the counter.

Unfortunately, I can't make an assessment of your web site to see if it's
of the same ilk, because it appears to be shut down.

Awww.....

Let's all say 'Too F...in Bad" in unison. Doesn't seem like you're getting
the
internet support you wanted!

If you don't like Radio Shack, why do you go there? Unless, of course,
you like the abuse you think you get, and go just to get more ammo!

Wait, I didn't come here for abuse, I came for an argument! Arguments
are two doors down on the right.

Hi,

Years ago, on a field day, I saw a local keying a homebrew contraption that he'd made whilst an operator in the RAF. It consisted of a conventional pump-handle key with a short piece of hacksaw blade clamped under the knob on which there was a sliding weight. After some practice he'd managed to produce quite respectable Morse out of this thing.

It appears that some years previously he'd been working a circuit from Gib back to the UK on which they weren't allowed bugs. In fact they got into trouble if caught using one. As it happened the RN operators at the other end were allowed them. After a time all the QLF's and "Put your mother on instead", got to them so someone invented this accessory which could be quickly hidden and pocketed when going off watch.

Cheers - Joe, G3LLV

The RAF banned bug keys because they were alleged to encourage bad morse
(lots of QSD ZBM2). The real reason was that the RAF could not be bothered
to splash out the cash to buy the keys and then train their operators to use
them properly.

It was bad enough training them to use a straight key, never mind a bug!

I'd appreciate that. I'll backchannel you with my email addy. I'd
suggest you obfuscate yours in the future - the posting and reply
address in your news reader. The spam bots mine these groups and
it's gotten quite ugly for some in the recent past.

You might alternately consider posting it to
alt.binaries.schematics.electronic under an appropriately
descriptive title.

I've got a copy of such articles, however, they don't
describe the form of the damper.

OK, which brings me on to the next question.....

Presumably, when the dot paddle is pushed, the centre of
the pendulum oscillation should be just at the point of the
contact closing, for then half of the swing will be contact,
and the other half will be no contact, so giving a 50-50
mark-space ratio?

Thus giving the reason why the dot contact has to be a little
spring, to allow "give" when the pendulum swings further
toward the already-closed dot contact? If this is so, this will
lay the way open to use a pair of contacts taken from a relay, and
to replace the spring with a little rod actuator.

I suppose that what I really need to do is to find someone
close to me who has such a key (or a Mecograph) and to spend
a couple of hours evaluating its operation!

Or maybe the HP 8640A, a lot cheaper.

If I built something myself, the question is, can any variable capacitor
actually tune in changes of just a few hertz at 2.0 Mhz. Is that possible
from a mechanical standpoint.

Probably what Reg is talking about is that the 1.0 normalized value
in the center of the Smith Chart lies on the purely resistive horizontal
line. Thus Z0 = 1.0 + j0 (normalized). Reg is probably saying that the
Z0 = 1.0 + j0 assumption is not valid at low frequencies for the average
transmission line.

Yes, and that is one of their disadvantages. An engineer can arrive
at a perfect quantitative solution without an iota of understanding
of the real-world qualitative physical processes. I personally am much
more interested in a conceptual understanding of the process than I
am in the accuracy of the abstract numbers which are the solution.
Graphs are a visual aid to conceptual understanding that equations
simply cannot match (even with a MENSA level IQ).

Cecil

I can se a couple problems. Both are mine. First, I should have written
that someone is wrong about Smith Charts being *FROM* use at low
frequencies. Second, there was no value in my posting something that was
already covered by others.
I sure agree with anyone who points out that Smith Charts shouldnt be used
where they arent designed to work. I like smith Charts and thats probably a
result of my poor academic education.

Richard Feynman, who had a decent IQ himself, said that he couldn't
approach anything analytically unless he managed to get an intuitive
feel for the thing first.

The good thing about "gut feel", from an engineering standpoint, is
that it's a good sanity check on the equations. My engineers sometimes
present me with an analytical result that just feels wrong to me, and
it usually - but not always - is. Graphs are also wonderful for
feeling how things work, just as analog meters sometimes are so much
more useful than digital ones.

Smith charts can be used to solve purely lumped-element problems, too.

I wonder if Smith charts have ever been used for analyzing 50/60 Hz
power grids. Their losses are fairly low.

Me too. I think that brains are fundamentally analog computers. I mean, when you shoot a rifle or hit a baseball, all sorts of complex adjustments have to be made for the situation, and they're not done numerically. I've acquired sort of this "analog" feel for electronics that gets me pretty close almost without thinking, close enough to be suspicious of calculations that aren't right. I can usually hit a component value or whatever to within 10% just standing up, which impresses/annoys the youngsters who, frankly, are so impressed by my instant numerical results that they accept them without checking... good thing! This analog instinct is a good complement to the math. It saves a lot of time, too, when you just know something will/can't work before you go to the trouble to prove it.

It must be amazing to be a Fermi or a Feynman who have this sort of intuition, but at astronomically higher levels. Fermi would glance at complex differential equations and just scribble the solutions on a blackboard, and his co-workers would spend days confirming his results.

>transmission line.

Cigar, I think. The imaginary term isn't zero, and in fact is dominant,
at low frequencies, and this applies for ANY transmission line that
doesn't have its inductance artificially increased, because:

Zo^2 = (R + jwL)/(G + jwC)

and at low frequencies jwL and G are negligible.

You don't use the mechanical cap to change frequency in that way.

What you do is this.....
1. Tune in with the mechanical cap in the normal way.
2. _THEN_ switch on the Huff 'n' Puff stabilizer.
3. The stabilizer will then hold your frequency to the nearest
Hz, 20Hz, or whatever is your step, using a _VARICAP_ across
your main tuning dial.

The essence is that the stabilizer is used to hold a previous frequency
and not to select a new one.

Well, I find it hard to believe that, in a weak moment, I visited the site mentioned below. It is obvious that a great deal of time and effort has gone into this thing, and to what cause? To save our rights? Me thinks not. What rights are we having trampled? You're right to slander RadioShack? That right is only in your mind. You are most likely a relatively well educated individual with many personal conflicts in his life and I feel deeply for you, but mostly your parents and family members. They most likely put up with your drivvel year after year and detest the site of you.

Why don't we just cut to the chase, and you explain, in a very short sentence or a very, very short paragraph what caused you to create this Radio Shack site that you claim sucks so bad that it has obviously destroyed your life and those of your loved ones? When They haven't harmed you. You are harming them by saying to the world that they suck.

I have enjoyed Radio Shack for many years. I was there when they became RadioShack, and I became a valued customer (I believe that because I still get free catalogs in the mail, not many do anymore 'ya know) to them and grew through the whole gammit of stuff they have added over the years and I must say that when I had a problem with a product, and that was extremely rare, they took care of it. In one case the manager returned my money because it was a last item and he couldn't replace it. A few years later when computers came along if this had happened, they could check all the stores in their system to see who still had it on the shelf and that store would mail it to me at my home. Is that cool? I say "Yea Verily".

I love Radio Shack. This little reply is probably enough to get you to open up KF5DEsucks.com I won't sue you unless you get nasty. All my friends will check in and post there I'm sure they will have comments to make there, they have a lot of freee speech to use 'ya know. I have a friend that can enlist, in moments hundreds of hackers that believe in not only free speech but free hacking tooo!! Free viruses', free wurmzs, 'n free other stuff too.

After that you can open up another site, KF5DEreallysucks.com

Or, you can channel your efforts into something productive and usefull and possibbly profitable for yourself and your suffering family which will no doubt heal many open wounds.

Don't know about your skills with building mechanical stuff. Many designs need to be able to work with brass & C.

This project is easily produced with paper clips http://home.online.no/~verner/Clippers.pdf and works well if you're not sending too fast.

Searching for "homebrew paddles" on Mr Google returns many links, and some of them have a detailed description of building a more sophisticate paddle set.

A solid power line fault usually causes removal of power
from the section of line exhibiting the fault. However,
automatic reclosure will often clear the fault.

And in conjunction with survey-grade GPS receivers, using CORS[1] data for post-processing, it makes for measurements that tend to have position accuracies within 2 cm.

CORS is worth a Google search all on its own, even if you don't have a survey-grade GPS receiver, just to see what can be done with one.

[1] Continuously-Operating Reference Station: survey-grade GPS station at a _very_ precisely surveyed location, collecting DGPS-corrected apparent-position data, which is periodically transmitted to the USGS for publication on their CORS website. My employer operates a CORS station, and I helped set up the data-transfer stuff.

What I was meaning is that a regular variable capacitor is a mechanical thingy, and if you were to hook up a frequency counter and varied a capacitor, could you in fact tune in 1 or 2 hz steps. For instance if you had any "play" between the spindle and the bearing, it might be impossible to acheive tuning at 1 hz intervals, the tuning might turn out coarser than that, because of the mechanical limitations if the capacitor. I get the feeling though that a good low value capacitor across the main tuning capacitor could allow smooth tuning at least say in steps no higher than 3hz and possibly as low as 1hz at 2.0 Mhz.

It would be no use designing a stabilizer circuit that is capable of tuning in say 3 hz steps, if the tuning capacitor could only manage a minimum of 10 hz.

A variable capacitor is not a digital component, so in theory even if the frequency tended to jump in appx 10hz steps, due to mechanical limitations, you can always get to within 1 hz just by fiddling with the tuning. But in this hypothetical case you could not tune smoothly in 1 hz steps. I was hoping to tune so I could put an interffereing signal just outside the passband 20 Hz wide. That would take a very small jump in frequency as one tuned the receiver. Thus the need for a stabilizer to lock on no greater than say 3 or 4 hz. Using as fine tune control a good quality low-value variable capacitor in parallel with the main tuning capacitor.

Yes, penny just dropped!! Why would I need a stabilizer to lock on at say 3Hz steps when tuning, when all I need is to ensure that I can tune in 3 hz steps. Then when I'm at the frequency of choice, switch on the stabilizer. What we are saying I think, is that I ought to be able to construct an oscillator/VFO working at 2.0 Mhz that allows me (with a good quality small-value bandspread capacitor) to tune smoothly in steps no greater than 2 or 3 hz, and when I'm at the desired frequency switch on the stabilzer that will hold it to within say 1 hertz over a good period of time.

It seems that I was going down the wrong path seeking a stabilizer with lock points every 3 or so hz.

Oh drat, I thought I had some kind of enlightenment, but I didn't did I.

I think I saw a difference between tuning with the stabilizer in circuit and
tuning with it out of circuit.

Tuning without stablizer in circuit: If I can tune in 1 hz steps with a
good quality variable capacitor, fine. But what happens when I switch a
stablizer on, will the frequency remain the same? Probably not, it will
jump a few hertz away depending on the locking point frequency. This means
you would have to have a stabilizer that locks on to within 3 hz say of your
desired frequency if you wanted really accurate frequency control (say 3 hz
is accurate). Could you get the dead on frequency by adjusting the variable

capacitor with stabilizer out of circuit, then putting it back in circuit. Not possible if the lock frequencies are fixed values. In fact this is the point. If the locking frequencies are fixed values, then in the worst case you can only get close to the desired frequency if these lock frequencies are
say 3 hz apart.

Tuning with stabilizer in circuit: What the diff. if the lock frequencis are at fixed points. Whether stabilizer is in circuit or out, if the frequency the oscillator settles to is at fixed points of say 3 hz there is no advantage or disadvantage.

True? BTW, I'm not vey familiar with stablizer circuits. I'm presuming that what a stabilzer does is enable very good frequency stability, but the downside is it restricts you to a set of frequencies, seperated by 20 hz say or less depending on the design.

I work mostly in time domain, so I need to convert s-params into
lumped device models, and it would be nice to have some software
(affordable software!) that does that. That's not really "dumbing
down" to me... it's the s-params that are dumb simplifications!

One trick I use is to visually estimate fet input and output
capacitances to see if a device is worth closer inspection. Just run
eyeballs down the S11 angle column and estimate the frequency (in Ghz)
where the angle hits 40 degrees. The reciprocal is Cin in pF. Ditto
S22 for output capacitance.

You don't turn these things on and off. The Huff n Puff is in operation at all times. It's just that when you tune in larger, faster steps, you are overriding the slow "corrector" voltage that is trying to bring the VFO to a frequency "step" that it can lock to. When you stop tuning, the VFO is pulled one way or the other by a small amount over a several second period to bring it to a lock with the nearest lockable frequency.

It is preferable to turn it off when tuning, else you may find
that the Varicap voltage has been pulled to one of its extremes
causing instability if the circuit determines that it is necessary to
pull further in the direction in which the limit has been reached.

Aug 2004:

>40 degrees ???

It's obviously a mathematical ruse, depending on cos(40) or tan(40) or
something like that (like tan(17.4) = 0.1*pi, nearly). I tried to
reverse-mathematic it, but my brane 'urts. (;-)

I've got 3 of them in operation, 2 since 1996 and Pete Lawtons since 1998.
None of them have an on-off switch and I have never seen one go to a rail
and lock up. (That is, AFTER clearing a solder "jumper" off Pete's board.)
In practice, the integrator voltage wanders in one direction and then the
other at pretty close to a statistical average rate.

For a 1 Hz step size and a 20 Hz IF bandwidth, I would recommend a DDS approach.

You need a precise LO tuning resolution and, I would think, the ability to tune BACK to that same frequency in the future.

==========

For recieve purposes, the low level DDS Spurs will not be a problem since they are something like 60-70 dB down to begin with and given your narrow IF it is not likely for a high level interfering signal to mix with a DDS spur anyway.....

Besides, you could run the DDS from 20 to 25 MHz, divide by 10, and reduce the spurs by 20 dB in the division process.

You are probably right. Perhaps I am over concerned about spurs and not
considering the obvious solution.

1410. rich cw for qrpp on hf

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-03 04:08:52 UTC
From: eternalsquire@comcast.net
Message-ID: <904dab11.0408022008.25a952e4@posting.google.com>
Source record: 24442

Hi,

This are some questions to those of you who are experts on modulation and information theory, and the related FCC regs for HF. I've done preliminary reading on CCW, PSK, and FSK, and so my knowledge about the subject is only fair to middling, but I think I might be onto something.

What I am interested in doing is creating a CW signal on HF can be keyed or copied by the human operator without computers, but that also contains enough extra information that simple hardware or even computers can pull discern it from noise.

The concept goes something like this:

On the transmit side, I start with a pure carrier. Then I vary it sinusoidally from +10 to -10 hertz of center, at a rate of 100 hertz. The carrier and the modulation are phase-locked to WWV.

That gives the ordinary listener a buzzsaw sound which is slightly larger in spectrum than ordinary CW but much smaller in spectrum than voice.

I then key the buzzsaw on and off like ordinary cw, as like 5 WPM. Sounds terrible, but at least it is CW.

On the receive side, I'll use a frequency discriminator to detect the variation in frequency of the carrier, to yield a 100 hertz tone. I could then borrow a technique from CCW and use the WWV time standard to phase lock with the incoming tone and thereby increase signal to noise ratio.

This gives me the two forms of redundancy with which to enrich the CW to stretch the range further.

Questions are: 1) is this feasable? and 2) could this method fall into the category on allowable modulation methods for HF, with or without some tweaking?
And 3) if it is feasable, is there anything more I can do to increase the redundancy for better receivability as a weak signal.

Many thanks,

The Eternal Squire

On-off keying of an audible tone on an FM carrier wouldn't be allowed on the HF bands.

This is OK, because you aren't going to see any advantages over plain-old CW, or coherent CW if you do all your synchronization.

By the way, is CCW still an active mode? I've thought for years that with the right DSP code you wouldn't need to lock onto WWV -- you should be able to phase lock to the carrier and "bit clock" of a CW signal digitally. In fact this is what some of the superior morse code readers seem to do.

DDS spurs can be a concern, depending on the application, and there are ways to deal with them.

For use as an Rx LO from 2.0 to 2.5 MHz, running at 20 to 25 MHz and then divide by 10 should be good enough. You will want to lowpass the output of the DDS after the divider, and with some input filtering to the mixer from the antenna, I would be surprised if there were any noticable DDS spur effects.

Personally, I am rather fond of RF attenuators that can be switched in between the antenna and the radio, they can "fix" a lot of things.

Including strong signals that could possibly interact with the mixer. I lean towards mechanical swiches, or relays. PIN diodes in a wideband input section of a radio can create other problems....

It seems to me that if the FCC allows Hellschreiber, it would also allow this. In making an improved CW, there would be very little difference, bandwidthwise, between OOK of an FM carrier and OOK of a pure grey 1200 baud narrow band FSK sequence. The latter is definitely legal, even if it would seem silly.

Source record: 24297

: > Has anyone experimented with making up large air-spaced
: > capacitors for ATU use ...

Yes!

Screw-thread with knob attached, supported on two 6mm I.D. ball-races. Large brass wheel gives large intertia.

Two nuts on screw-thread push wedge-shaped single-sided copper-clad boards into stationary wedge-shaped single-sided copper-clad boards. Capacitance up to 500pf. Use nylon blocks to mount stationary boards. Has a very nice feel to tuning, just like the old AR88 - quick spin and watch it continue to to other end under it's own momentum.

: > ... out of Aluminium Foil?

Only as experiment. Too floppy! Read this experiment in a book and gave it a try. It worked, but a bit clumsy:

Experiment was two strips of aluminium glued 1/2-way around a plastic pop-bottle. 1/2-fill bottle with water. Lay it on it's side and rotate. Works well - BUT - water sloshes around - difficult to tune. Read that you can 1/2-fill with water and the rest oil to damp the oscillations. I chucked mine in the bin.

Pawel,

Hi,

This are some questions to those of you who are experts on modulation and information theory, and the related FCC regs for HF. I've done preliminary reading on CCW, PSK, and FSK, and so my knowledge about the subject is only fair to middling, but I think I might be onto something.

What I am interested in doing is creating a CW signal on HF can be keyed or copied by the human operator without computers, but that also contains enough extra information that simple hardware or even computers can pull discern it from noise.

My motivation for this is that not everyone in the world has access to a computer, but even people in third-world countries can junk a stereo or a tv for the parts.

The concept goes something like this:

On the transmit side, I use two carriers 20 hz apart, and alternate them at 100 hz, basically a pure grey mark space sequence.

That gives the ordinary listener a buzzsaw sound which is slightly larger in spectrum than ordinary CW but much smaller in spectrum than voice.

I then key the buzzsaw on and off like ordinary cw, as like 5 WPM. Sounds terrible, but at least it is CW.

On the receive side, I'll use a frequency discriminator to detect the variation in frequency of the carrier, to yield a 100 hertz tone. I could then borrow a technique from CCW and use the WWV time standard to phase lock with the incoming tone and thereby increase signal to noise ratio.

This gives me the two forms of redundancy with which to enrich the CW to stretch the range further. The benefit would be to recognize the signal from the pattern of the switched carriers.

Questions are: 1) is this feasable? and 2) could this method fall into the category of digital modulation methods for HF, with or without some tweaking?
And 3) if it is feasable, is there anything more I can do to increase the redundancy for better receivability as a weak signal.

Many thanks,

Andrew

The purpose of this is to design a "better CW" which does not require
a computer to receive, only frequency comparators and analog sync
circuitry. Not everyone in the world has access to a computer,
especially in 3rd world countries. However, operators in those same
3rd world countries could certainly get parts by cannibalizing TV's,
VCR's, or boom-boxes.

I see your point, but what about OOK of a grey pattern of alternating
carriers 20 hz apart at a rate of 100 hertz, with synchronized
alternation? This would fall under a degenerate case of Hellscreiber,
which indeed is allowed by the FCC.

1417. YIG-tuned oscillators and the ADF4107

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-03 07:23:06 UTC
From: John Miles <jmiles@pop.removethistomailme.net>
Message-ID: <MPG.1b78dd34eb90cdd69896f4@news-central.giganews.com>
Source record: 24299

Just wanted to post a brief update on some ongoing work. A few months ago, a couple of people were speculating on adapting the KE5FX/VK6BRO DDS/PLL synthesizer project (http://www.qsl.net/ke5fx/synth.html) to drive a YIG-tuned oscillator for better spectral purity and wider frequency coverage. The ADF4107 chip seemed like a good starting point, since it's specified for coverage from 1 GHz - 7 GHz. I ordered some samples from Analog Devices at the time, but only just got around to trying them out over the past few days.

The ADF4107 is pin- and software-compatible with the ADF4112 used in the QEX article. However, its upper frequency range is 7 GHz instead of 3 GHz; its RF input is 5 dB less sensitive; and it requires a 2.7-3.3 volt supply (as opposed to 2.7-5.5 volts for the ADF4112). Upon installing the ADF4107 on a DDS/PLL synth board, some rework was necessary to power the PLL chip from the DDS chip's analog 3.3V supply. 6.8K/10K voltage dividers had to be inserted in the 5V PLL control lines; a 68/51-ohm voltage divider was used between the 5V LT1016 comparator and the ADF4107's reference input; and a 2N2222 was used to turn the 3-volt lock-detect signal into a TTL-compatible signal for the parallel port interface.

Modified (i.e., totally hacked-up) DDS/PLL synth board photos:
Thumbnail (50K): http://www.speakeasy.net/~jmiles1/ke5fx/ddsyig1.jpg
Full-size (900K): http://www.speakeasy.net/~jmiles1/ke5fx/ddsyig1a.jpg

I have been using an Avantek AV7028 YTO, specified for 2-8 GHz coverage, for R&D on this project. I remember paying $700 for this thing back in the early 90s, before eBay made YIGs available for 5% of that price! My target output range is between 2 and 6 GHz. Any higher than 6 GHz and the YTO, which doesn't have the correct mounting hardware, gets too hot. I did verify that the 7 GHz limit of the ADF4107 is a hard limit; I couldn't push it much higher than 7.2-7.3 GHz.

The YTO's main tuning coil was biased with a 16-bit serial DAC (MAX541), driven by a PC parallel port separate from the one connected to the DDS/PLL synthesizer. I wrote a quick-and-dirty Win32 console app to pretune the YTO to within roughly +/- 10 MHz of a given output frequency. The observed linearity was excellent -- I thought I'd need a large interpolation table for the DAC, but you can pretty much draw a straight line between the DAC constants for 2.0 and 6.0 GHz and land within a few MHz with a single "lerp" calculation. YIGs are amazing parts.

2-6 GHz, +14 dBm YIG oscillator/driver assembly:
Thumbnail (50K): http://www.speakeasy.net/~jmiles1/ke5fx/ddsyig2.jpg
Full-size (900K): http://www.speakeasy.net/~jmiles1/ke5fx/ddsyig2a.jpg

Phase-locking was achieved by tuning the YTO's FM coil with the output of the loop filter in the DDS/PLL synthesizer. Because YIG oscillators and filters are tuned by current rather than voltage, it was necessary to add an emitter follower after the OPA27 to turn its output voltage into an equivalent current through a power resistor. Overall tuning sensitivity, which is 70 MHz/volt with the ROS-2150VW VCO, was reduced to about 2 MHz/volt when driving the YTO's FM coil through a 150-ohm resistor.

I plugged the 2 MHz/volt KVco figure into the design equations in the article and calculated component values for a 2 kHz-wide filter, leaving everything else alone. I removed the VCO and output MMIC from the synth board and routed a 1" section of hardline directly to the ADF4107's pins from what used to be the output jack. The loop fired right up and seemed to have no problems locking across the entire range.

At about -93 dBc/Hz at 10 kHz from the carrier, the phase noise at 2 GHz was better than the ROS-2150VW's observed performance at 1 GHz.... and there is still a LOT of room for improvement. The 2-kHz loop bandwidth is too wide, given the YTO's superior phase-noise specs compared to the ROS-2150VW. Worse, my power splitter becomes very lossy above 2 GHz, degrading the ADF4107's noise specs by several dB at 4-6 GHz. Anyone got a 2-6 GHz small-signal 2-way splitter they're willing to sell me?

I also have some kind of transient stability problem in the voltage-to-current driver circuitry associated with the DAC, which I will need to resolve before calling the experiment an unqualified success. As things stand, it takes several sweeps to get a clean graph. It was a relief to see that harmonic locking at the lower end of the band wasn't a problem, although again, I can't evaluate this without a flatter power splitter.

Even at this early stage of development, the performance is within spitting distance (6-8 dB or so) of an HP 8672A synthesizer ($40,000 circa 1986). It shouldn't be hard to close the gap once the bugs are worked out and I understand more about what I'm doing.

There is probably another QEX article in here somewhere. Not much has been written about the care and feeding of YIGs, and it's an interesting topic for serious microwave experimenters, now that the parts are affordable and easy to come by on the surplus market. More later, hopefully....

Here's another idea for you - you could use the main tuning control for "rough" tuning, then use push button control to move the frequency up or down one lock point. E.g. if you have lock points 10Hz apart, you could arrange for two push buttons, to increase or decrease the frequency by 10Hz. In this case "all" that is required is for this function is that pushing a button delivers a sufficient pulse to the integrator to move the VFO frequency past the half-way point to the next lock point. The stabiliser will then move you the remaining couple of Hz to the next lock point.

I have not tried this and I imagine it would need to be adjusted carefully to cause it to jump only precisely one step. Linearity of the integrator and tuning voltage resp. freq would also need to be reasonably good. But I do feel that it would work well: the applied pulse needs in theory to move the VFO (in my example) by anywhere between 5 and 15Hz, and the stabiliser will act to bring it back to the desired 10Hz move.

That could be quite a nice feature in your case, if you find that you want to move 10Hz (or whatever lock distance you choose), just to move some QRM outside the IF passband.

Huff Puff circuits are a lot of fun: a simple circuit with endless variety and possibility for experimentation. DDS is a little more complex and also poses the risk of spurs, though as others have mentioned their effects can be mitigated.

Hi all,
Has anyone had experience with the Siliconix Vmos VN88? I've got a pair running as a 1W linear on 40M and 80M but I've no idea of their potential. They seem to have a much higher input impedance than equivalently powered bipolars but I really don't have much of a feel for this.
Any ideas on maximising ouput would be greatly appreciated,
Alan

They are obsolete now, I'm afraid. Not exactly a great choice for this
application. You'd be better off picking a newer, more suitable Mosfet
and starting from scratch if it's more power you're interested in.
BTW, it's a characteristic of all Mosfets to have a *very* high input
impedance as virtually no current flows through the gate, they're very
easy to drive, especially for types with a low gate/source capacitance
figure.

OK - a friend of mine used a similar technique for his
Tesla Coil (5ft sparks!). His original attempts using the
approach recommended in Wireless World of wrapping
alternate layers of polythene and aluminium (aluminum for
the Yanks who neither speak nor spell English!) failed because
when the thing was folded up, there were air voids around the
corners which causing dielectric failure - arcing in the air charred
the polythene and then the polythene failed.

Having now located a local supplier of aluminium sheet, and a
friend who has a guillotine, I'll try the wedge approach recommended
by the other contributor, whose name/callsign escapes me for
the moment.

NEXT QUESTION

"L" configuration ATU's seem to need switching to change the capacitor
(and the coil) from serial to parallel connection. Has anybody played around
with making their own knife switches? Such switches would fit in with my
plan to
control the ATU via nylon rods from the shack. (In order to satisfy The
Station Manager/SWMBO, I propose to install a short length
of picket fence to hide all the rods)

: Wedge shaped?

Yes, wedge shaped. It makes for smaller adjustments at lower capacitances.

: 1. For ease of construction - two triangles guillotined

: from each rectangle?

That's exactly what I mean.

: 2. For ease of fine adjustment?

Yes.

: 3. Do you mean isosceles wedge or right-angled triangle?

Right-angled.

: 4. Sounds great!

Works great, too. Just do NOT apply sideways pressure to cause the boards to "bind", otherwise the tuning can become a little "jerky".

Actually they have significant loss. It turns out that a t-line with loss
has a complex characteristic impedance, not just resistive, so they have to
match complex Z0 's

Jim

There is a big benefit to someone as ill informed as myself when these
discussions involve guys who are actually informed and present
understandable info for "jump starting" guys like me.
I probably wouldnt have read the posts if I'd started reading only *one*
side, without some kind of contradiction.

Jerry

Well, that was Jim yer replyin' to, but since you're not Paul
Burridge, that's perfectly fine and I'm glad you did. It reminds me
that back when that big Canusa (not Canusa TM) happened, the poster
that goes by Ralph and Diane IIRC wrote a nice piece about the
dynamics of power systems, line reactance and all that.

That's a new twist for me. You saying we should slap each other
around some more? ;)

Just to summarize the part that's IMO most relevant to Burridges
learning disability, Chis Bowick, on pp. 105 - 107 of Secrets of RF
Design shows an example of a Z plotted on the Smith chart and he
labels it with the complex number representing a Z load and it's
reflection coefficient, both of which can be read directly off the
chart. He then give conversion equations that can be used to find a
numerical answer.

What bugged me is that it's so easy to errantly think that a rect to polar conversion on the Z would yield an S param when in fact doing that just gives you a polar representation of Z, i.e. |Z| = sqrt(R^2 + X^2) and Z ang = atan(X/Y)

We Yanks are even more linguistically declined than you think. In addition to misspelling and mispronouncing aluminium, we also call polythene "polyethylene". Two countries separated by a common language, indeed.

Now, it's time for a snack. But where did I put that spotted dick. . . oh, yeah, there it is in my fanny pack.

>
>I wonder if Smith charts have ever been used for analyzing 50/60 Hz
>power grids. Their losses are fairly low.

The origin of the Smith Chart happened when a relatively junior
engineer (Phil Smith) was assigned to study audio frequency
telephone line response at Bell Labs in the 1930s.

The very first "Smith Chart" is dated 22 April 1931 (a rectangular
format) while the first recorded circular format appeared in McGraw-
Hill's Electronics magazine in January 1939. An improved version
with sliding axial scale appeared in Electronics magazine in
January 1944.

There wasn't a lot of microwave work going on in the electronics
industry in the 1930s and 1940s compared to the post-WW2
period. :-)

A Smith Chart is simply a very convenient way of graphically
displaying complex number quantities of impedance and
admittance quantities. Yes, it is possible to do it all pencil-
and-paper with a slide rule and sound very noble and arty about
it but only damn fools take the long road to spend several months
of desk work on a problem that can be solved in a day's time.

THE authoritative source on the Smith Chart is found in "Electronic
Applications of the Smith Chart" by Phillip H. Smith, MTS of the
Bell Telephone Laboratories, Inc., prepared under the sponsorship
and direction of Kay Electric Company, published by McGraw-Hill

1969, Library of Congress Catalog Card Number 69-12411. 222pp.
Includes four overlays suitable for xerography or Ozalid copying.

For most simple tasks, an H-P 32 S II pocket scientific calculator
can do all the complex quantity basic arithmetic in a few keystrokes.
That includes conversion between impedance <-> admittance. Most
handy.

The Smith Chart can be used at ANY frrequency not DC.

Len Anderson
retired (from regular hours) electronic engineer person

I think I agree with you. The Smith Chart is not frequency dependent. The models regarding RF transmission line impedance do start to break down at "low" frequencies. This has nothing to do with the Smith Chart. You get the same bad answers with analytical method using bad models as you do with a Smith Chart. IOW, Reg was wrong. The Smith Chart is not limited to solving only transmission line problems.

I regard polar numbers as complex, especially if the angle is not zero.

Of course; polar format is just one way of writing complex numbers.

Why don't you use a DPDT relay to change configurations of the "L" network. I have done that on a couple of occasions and it works well.

The fun of _REAL_ Ham Radio is doing things yourself.

(It's CBers who buy off-the-shelf automatic switches such as relays. :-))

I have in mind to make up a big rotary switch (lots of luvverly brass)
to cycle through the range of permutations possible.

Another Question

What's a good variable inductor to place in the ATU? I saw an interesting
one recently where the inductor seemed to be a tape where the unused portion
was wound onto a conducting drum, rather reminiscent of the fusee in
horological movements.

Hi All;
Here is an interesting set of Five(5) NOS N-U control pots that were made during WWII(1942). They are Cat#2MEG-tx(tapped) with on/off switch if activated by pulling a tab!
They are Sav-a-Shaft design which means that "to help out the war effort" you cut off the old shaft & tap it into the new pot with has a collar.
Switch is rated at 3A@125v or 1A @250v
I have not tested them because they are nos in original boxes.
Anyone need any?
5 for $20ppd!

Source record: 24329

On lots of polar and near-polar ionospheric paths (like Tokyo to Ottawa) there can be considerable amounts of Doppler shifting and spreading of the signal, even under "normal" conditions. I regularly see plus/minus 10 hertz of spreading, sometimes asymmetrical. This shifting of the received carrier freq will add noise to your detection system. And if the fading rate of the signal approaches your nominal 100 hertz frequency you might never be able to lock onto the received carrier, even with the WWV reference.

But this in on near-polar paths, while transequatorial and ordinary short paths won't be bothered by this sort of thing except under the most extreme ionospheric conditions. So it sounds good. Why not build a simple system and try it, as 'proof of concept'. A real-world experiment is always better than a theoretical straw-man.

Both or more. As Jerry states, these threads are of interest to all
general readers, I copied a couple of posts to the saved folder for
later perusal. So please don't let PB's bad behaviour discourage them.
I only suggest that PB be ignored when he flies off the handle and
starts dissing perfectly good replies because they're not what he
expected or he doesn't understand them. Somehow he manages to generate
huge threads of inanities and then gripe about wasting his time :-)

>The fun of _REAL_ Ham Radio is doing things yourself.

Of course, I have been doing that for 50 years.

>(It's CBers who buy off-the-shelf automatic switches such as relays. :-))

Relays have been around for 100 years. In order to make your own relay, you would need the capability of making your own enameled wire, as well as smelting metals for making the movable contacts, as well as some other things I have not thought of. Why in 2004 would you want to make your own relay?

>I have in mind to make up a big rotary switch (lots of luvverly brass)
>to cycle through the range of permutations possible.

How are you going to mine the metals and smelt that thing?

>What's a good variable inductor to place in the ATU?

Variable inductors are difficult to homebrew even if you can buy the wire, coil form ect.. If you have to homebrew the wire, as well as the coil form, and the movable contact, even more difficult.
As I see it the answer to most of your questions is how elementary do you want to get? A relay is very elementary, but I don't homebrew my own, neither variable inductors. I didn't fabricate the mosfets in my 1200 watt homebrew amplifier. I did the design, and building as all my HB projects. Am I a CB'er:-)?

So at last you admit you got it wrong. It's about time. I can see where you f*cked up, Mike. I eventually got to the bottom of your elementary reading error in mistaking the relevant equations on P.107 for the simple ones on P.105 (from memory). Anyone can make a dumb-ass mistake like that, but it takes a *man* to admit it and apologise for going off so rudely on half-cock.
Jerry: you're reply wasn't correct but that doesn't bother me. You gave it in good faith and with the best of intentions. There are a lot of guys here who could learn from you where manners and good faith are concerned.
G'nite all...

I changed to Activ8 after someone mispelled it. I thought it was a
more proper way to convey "activate" as opposed to "active 8". I got
tired of looking at it and stuck the "e" back in there.

Active8 - when I throw the switch, it works.

Just the polar conversion part which I recanted long ago - probably
in my second post. I haven't reversed my original statement that the
Z can be read as S directly off the chart *as is* if you measure the
vector and project it to the unit circle. The equations on p 105 are
irrelevant to the original question.

> It's about time. I can see
> where you f*cked up, Mike. I eventually got to the bottom of your

That ain't the case. I was looking at the chart and suggested a
polar conversion, which I later termed a "knee jerk" response.

> Anyone can make a dumb-ass
> mistake like that, but it takes a *man* to admit it and apologise for
> going off so rudely on half-cock.

I slapped you around because you couldn't just accept that the
graphical solution works. Also, you're slow on the uptake (remember
not understanding those colored arcs you posted) and it might just
be possible that serious electronic design (as opposed to twiddling
values in spice) isn't for you. I'm one of those assholes that isn't
satisfied until I can derive the design equations from basic
principles and all that. Despite the work required to aquire that
ability, I keep at it until it's second nature.

Just about all the power FETs have a very large input capacitance (which changes radically during the RF cycle). This makes driving them a real challenge, with the job getting harder as you go up in frequency. I believe there was a series of power FETs designed specifically for RF which have lower capacitance, but they were expensive. I've successfully driven a single IRF511 up to 15 meters in class C with reasonable efficiency by using a complementary-symmetry stage for very low driver output Z. You can find the circuit in _Experimental Methods in RF Design_ (Fig. 2.99), along with some other ways of dealing with power FETs.

If you possibly can, run a power FET at 24 or more volts on the drain. Among other benefits, it reduces the drain-gate capacitance which is a major help.

Please help with data for Siemens BB113. Discovered that I had many such diodes, but haven't the faintest clue how to use them, tried to search, but found very little useful info, only that it is SOD37, but no mention for what is SOD37. So at least I need the connection, but better would have been a complete pdf file

The semiconductor company formerly known as Motorola has had RF power
FETs up to VHF since the late '80s, they probably have them higher if
you can figure out the name.

There are also RF power JFETs out there. I suspect that any real player
in RF finals will have RF FETs of some sort or another. They tend to be
optimized for moderately high power (500W) and high drain voltages (50V).

Jumping in here with only knowing half the subject already discussed. NDB (Non-Directionsl Radio Beacons) as I know them are an aviation navigational aid. They are not used to the best of my knowledge as long range navaids but are used for instrument approaches into airports or as a component of other types of instrument approaches. I would reearch if what you propose could present a risk to the flying public.

Martin,

Thanks for the comments. Yes, I do want to build a proof of concept,
but I needed help in getting as many people to either poke holes in the
theory if possible or suggest improvements.

I've gotten opinions back from a few people in private.

One of the opinions is that a narrow shifted fm signal varied by 100
hertz is not allowed on HF. I think I am describing a form of F1
modulation, which certainly is allowed on HF alongside A1 modulation.

Even if that person is right, I could work around that by instead
alternating with two carriers seperated by 20 hz. Each carrier would
be on for 10 milliseconds before switching to the other carrier. It
would be a form of FSK containing nothing but clocking information at
close to the maximum baud rate allowed on HF. I would then on-off-key
the FSK.

I can extend this and even alter the duty cycle of shifting between
the carriers to contain another form of clocking information.

Can you suggest any further improvements or changes?

Thanks,

The Eternal Squire

HF Linear Amplifier 80-10 meters single Eimac 4-400 with
separate RF Deck and Power Supply.
Nicely built the RF Deck looks like a Henry.

Output is adjustable with a simple change in value of a grid resistor.
Spare Eimac 4-400 NOS - tested however no hours,
both tubes in great shape.
Prefer pick up - the powersupply is heavy. $275

Thanks for that. I'm only using VN88s because I had some - there are no nearby RF FET shops here :)
I'll play around with the drive circuitry a bit more and see what I can get. I'm ony using 15V on the drains at the moment so I might bump that up to 24 or so.
The main thing I like about FETs is their thermal stability. I fried a few BJTs because it's hard to stabilise them in breadboard setups.
Thanks also to the others who replied.

I wonder what the standard screw threads in a Vibroplex
are, bearing in mind its genesis of 100 years ago?

I imagine that it wouldn't be BA, as this was a Britland standard.

I've sorted through the junk box for this project and have located
a gert lump of black-rolled steel for the base, and quite a few offcuts of
brass for all the bits.

What metal is the Vibroplex pendulum made from? I've got a piece of
thin brass which might do the job.

Kinda vague on what you mean by Vibroplex, the only thing I know with
that name is the keyers. In which case, and having just looked at
what remains of one, 8-32 is about all I see until I turn it over and
then see some 6-32 screws holding the stantions from the bottom.
Pendulum springs were spring steel, contact springs appear to be
phosphor bronze, could be wrong. Pendulum weight is steel, nickel
plated on one, brass, nickel plated on another. Pendulum rod appears
harder, maybe music wire, might have been some other, but it's got
some toughness to it.

Exactly Ron,
My limited research has turned up a number of excellent RF power fets
and application notes for HF linear amplifier use as you mention.
Problem is they are gawd awfull expensive and hard to source. One does
not want to fry too many while experimenting. At $1.40 each and with
impressive specs and the IRF820 looks to be an attractive candidate
for RF experimenters. I use the IRF510 as a base line for comparison
since there are several linear designs out there using them up to 28
mhz. The IRF820 is a newer generation mesh overlay fet with extremely
fast dv/dt and Td(on), Rt, and Td(off) times comparable to the IRF510.
It has a higher dissipation of 80w verses 43W for the 510 but a higher
input capacitance of 315pf verses 180pf for the 510 which may present
the biggest design challenge for use up to 28mhz. Best of all its a
500V FET meaning a high drain voltage can be used reducing the effects
of gate capacitance change under dynamic conditions. At 170 volts Vdd
the power supply could simply be rectified mains with no expensive
transformer or RFI generating switching stuff and the higher impedance
would make matching to 52ohms easier and more efficient. A 4 fet 300W
at 170 Vdd amp works out to 48ohms output Z. Yup, its starting to look
like a tube. The link I posted showed a single IRF820 making 60W SSB
on 40meters. I think it could do better. A pair, or even two pair in
push pull at 170 volts Vdd could make some serious RF power. I plan
to try some in the near future and possibly come up with an amplifier
design. Even 160, 80, and 40 would be acceptable to me with 20m a
bonus. I would love to hear what others are trying in this regard.
I'm registered with QRZ and RAC. A 40 meter home brew net would be

great.

Source record: 24258

I once made a capacitor from Al foil and the cover of a log book. It was
the cap for a neon bulb relaxation oscillator. I had an old photo-flash
300V battery. Since the foil would be attracted together more as the
voltage rose, you could hear the tone.

I agree about the experimentation. It could be instructive seeing, in practice, how fine the fine tuning control could be made to work. Might give DDS a bit more competition.:c) I'm not as yet sufficiently educated in theory of stabilisation, well, in electronics generally, so it might take me a few months. If I start now I might have something up and running by Christmas, and probably by next spring with all the other stuff crying out for attention. :c)

No need for procrastination, grab a copy of the "Fast " digital oscillator stabilizer by G7IXH, and print your PCBoard from it. Order what parts you don't have and while they're coming from Thief River Falls, etch and drill your board. Ought to have it operational by this time next week. No added PLL phase noise and stable like the rock of Gibralter.

A homodyne, synchrodyne or super-regen would radiate and give a false
position. Other types of receiver would basically be OK, but I would
ensure that the LO wasn't in-band even so, if the receiver used a tewb
LO.

Non-precision approaches, perhaps, when they are close to a field. They are
little used today. They were intended for medium range navigation, replaced
by the VOR. I get a few on my 706 and 40M inverted Vee.

Like any form of FM, your proposed system will exhibit
threshold effect. Below threshold, it will be WORSE than
a carrier detect system. The more you spread out the signal,
the higher level the threshold effect will occur at.

If you simply apply FM at the transmitter and take it
off at the receiver, you have an analog spread spectrum
system. The modulation has no effect on performance,
or may make it worse due to selective fading.

I doubt that your couple of milliwatts would outshine the true VOR signal,
especially given the sort of antenna you're likely to be running.
There are already all sorts of accidental emitters in this band, and they
aren't causing any trouble.

I don't understand what threshold effect is.

I'm sure everyone saw the FSK/PSK alternative to the analog FM scheme,
what would be the effect of thresholding would be on either alternative?

Giving the system more thought from input by other people, I am
probably leaning toward a repeated FSK/PSK pattern.

I worked out a pattern that shifts both in frequency and phase
at regular intervals:

where each underscore character is one time unit, and each
vertical bar is one frequency unit. Ignore the space in between
the underscore characters.

I drew up some timing diagrams, and I found no less than eight
orthogonal logic conditions by which I could identify the
presence of this pattern in at most 10 time units.

It would seem to me that if the incoming signal satisfied even three
of these measures for any given time unit, I could conclude that that
signal matched the pattern and emit a logic high. That may defeat many
problems introduced by a high noise floor.

That logic high could drive a tone generator to headphones. If each
time unit were 10 milliseconds, then a dit would be easily audible
if the signal satisfied the pattern at 5 out of every 10 time units.

More thoughts anyone?

Not really, I think that your attitude is a poor one, for if
we decry any attempts at home construction then we surrender
Ham Radio to the Mongolian Hordes of CBers-Masquerading-As-
Radio-Hams by which I mean those second-class citizens who
buy their complete station from a shop, and even send it back there
for repair when it malfunctions.

It is certainly a most regrettable attitude for a NG whose emphasis
is homebrew.

NOW AVAILABLE ** New Program "RADIALS2.exe"

This program takes a fresh, revolutionary look at the design and performance of a set of shallow-buried ground radials. Gone at last are the days when 118.5 was a sacred number.

A radial wire is considered as a lossy transmission line, there being no point in having it any longer than that at which its input impedance Zin has converged on its characteristic impedance Zo. The current flowing in the line at that distance from the input end is clearly small enough not to warrant extending the radial any further. With a crude knowledge of the resistivity and permittivity of the soil the greatest practical length of radial wires can be calculated. The number of radials can then be estimated on the logical grounds of economics versus antenna + transmitter radiating efficiency.

Download program RADIALS2, 53 kilobytes, in a few seconds from website below and run immediately.

True, but the subject line refers to NDB's not VOR's. Good luck even TRYING
to interfere with an NDB. Even if you do manage 50 or 100 watts and a
decent antenna, nobody's listening. 'ceptin some hams and perhaps a random
pilot who wonders if his ADF is still working. They can always use an AM
station (ADF's tune the AM band) if they can't get an NDB.

Hi,
maybe the problem with machine-Morse-reception is our comps are binary-oriented and Morse code is ternary-oriented.
The morse code in fact uses three different symbols: dih, dah, end-of-symbol space. The relative timing of this symbol set should be 1:3:3 (or 1:3:2 ?!), but it may vary with operator skills and the absolute timing values vary with the code speed in wide boundaries. The character lengths is selected so that frequent symbols are short, which enhances the overall speed. It is fully acceptable for our ears, but hard for computers.
The ASCII code uses two symbols: mark, space. Their relative timing is 1:1, the absolute timing is given in steps (300 Bd, 1200 Bd, 9600 Bd, ...) and usually controlled by crystals. All characters have the same length. The start and stop of each character is clearly defined. It is perfect for computers, but hard for our ears, even at some 10 Bd (about 12 WPM). And it is hard to send ASCII on a classic Morse key either.
IMHO the question is to develop a code, which is acceptable both for ears and for computers, not a new sort of modulation. Some sort of Morse-like code, carrying enough internal timing information, with start and stop clearly defined ...

First, Rick,
I beg to differ. At this low mod index there'll be no threashold effect. Narrow band FM behaves like AM. I also believe it is true that as the system bandwidth gets *wider* the threshold goes lower, just as does the capture ratio. FM broadcast receivers have capture ratios under a dB. Narrow band FM as we use on 2M are higher.

Now general comments for "Mr. Squire":
I just came on board, so don't know if this has been said. My initial thoughts:
Yes, it would sound like a T6 CW signal.
This signal is (approximately) 200 HZ wide, not 20Hz. (which I believe is your implication)
The 100 Hz FM modulation produces first sidebands at + and - 100 Hz. So it is considerably wider than CW. To receive the 100Hz modulation, you need a 200 Hz wide receiver. Narrow band FM has no advantage over AM...(or CW since it's pretty much the same thing).
The FM modulation index of the proposal is 0.1 making the sidebands quite low in amplitude. Only the first pair is significant being only 5 percent the level of the carrier. Therefore, a vast majority of the transmitted power is still in the carrier.

Index	Sideband level 1st	2nd
0.1	0.050	0.001
0.25	0.124	0.008
0.5	0.242	0.031
1	0.440	0.115

(Done with Excel J1 & J2)

This shows amplitude, so the power in these sidebands is 0.2 percent or
26 dB lower than the carrier (forget if that is both, or each sideband).
I'm not familiar with CCW (don't even know what it is--must assume
synchronous CW), but a method to sync the transmitted signal (both the
on-off keying and the modulation) with WWV can't be simple. This equates to
equipment and why not just get the computer back into the equation.
Then there is the Doppler and slow phase shift of the ionosphere,
mentioned by Martin above. I believe synchronous systems assume the desired
signal will remain relatively un-disturbed in transit. When doing the last
ARRL frequency Measuring Test, I was watching the W1AW CW/Carrier signal
phase shift back & forth on the scope...cool! This is only Illinois to
Conn. You can watch WWV shift as well. Therefore, phase coherence of the
carrier is out of the question. Phase coherence of the modulation will
suffer the same *TIME* shift problems as the carrier and be much less of a
problem, since the frequency is so low...I think. WWVB is more stable, but
you still have to sync both the Tx & Rx and that equates to hardware of some
type be it computer sound card or dedicated logic.

I'm not sure what the desired advantage of the scheme is.... Low signal to
noise performance like PSK-31, but without the computer? The Brain does
that amazingly well...

School's a long way back, but I'm pretty sure an advantage of FM comes
as you go *wider*. As the SYSTEM bandwidth grows, you do, indeed, take-in
more noise, but all these noise components are not correlated with each
other at the receiver - the signal's sidebands are. That is, the sidebands
will all add to the demodulated signal at the receiver, whereas the noise
'does not add' (at least as much).

This, unfortunately sounds like the old April "Micro band FM" concept.
Deviate voice only a HZ or two and fit millions in each band then, by
ordinary receivers, you'll be un-detectable as nothing but a carrier.

Gee, I thought narrow band FM (same width as the "usual" voice signal,
which these days is either SSB or AM) was allowed on HF... Better look over
the latest Part 97.

Digression...
By the Way... A large part of the apparent ability of PSK-31 to operate
"below the noise" is the fact that the receivers we use are much wider than
the signal and, therefore, capture more noise than the detector in the sound
card does. The sound card has a narrower filter (calculation) to achieve
the narrow bandwidth performance. We hear noise the sound card filters
out. This is also why is it bad practice to run more power than needed.
If there is a strong signal near the one you are copying, and within your
receiver filter, it will operate your AGC and reduce receiver gain for all
signals in your bandwidth, including the one you are copying.

OK. lesee what comes of this...

"Squire",

1st, Threshold is best understood at an intuitive level with the explanation
of the noise in my previous post. Because the noise is not correlated to
produce an output, but the modulation is, the noise does not contribute as
much as the desired sidebands, so as soon as you have enough sideband power
at the receiver that isn't corrupted by the noise, you get signal out. The
less the noise is correlated (the wider the bandwidth) the quicker this

happens as the signal increases out of the noise.

On to your new system:
What you now describe looks almost like PSK31, but somehow coded in Morse rather than the one used for PSK31. If the "warbles" are Morse based, then the CW operator should be able to decode it. It won't be as easy as CW, though. The warbles are pretty subtle.

I see two things in your description.
1 - Is that it is still no better than CW bandwidth wise for the ear and you'll need a very narrow Rx to reap the benefit. In addition, the warbles are much more subtle than on-off keying -- for the ear.
2 You talk about "orthogonal logic conditions", which sounds just like the code used for PSK31, no?? It has codes for each character which are unique and not confused with each other --a.k.a. "orthogonal". So, on the detection side you still need the hardware (read computer sound card) to decode it for your "full" system.
Sounds like you re-invented PSK-31 (which can sort of be decoded by ear). Except, I think there may be a conflict trying to find the PSK patterns which fit within the Morse characters and remain orthogonal.
Hmmmm How about only "processing" this with the sound card to do the narrow band filtering then send it out as audio tones for the final decoding by ear for the last error correction step.

Hi;

Does anyone have a recommendation for shareware/freeware schematic and pc layout programmes? Particularly something that goes together to help or auto-route from the schematic programme - and produce a Gerber plot file. I've been out of it for a long time (last time I used schematic software it was Futurenet on an IBM PC). I have a few circuits that I would like to get on PC boards at this time. Thanks ever so much.

Cross-posted to: alt.radio.scanner,rec.radio.amateur.homebrew,rec.radio.scanner,sci.electronics.design

Still plenty of pilots who use NDBs to do instrument landing approaches. Especially at rural airports. GPS is all the rage now, but many rural airports don't have a published GPS approach yet. And, an FAA "approved" GPS is very expensive (roughly $4k installed and certified), so many aircraft owners don't have one yet.

http://www.cadsoft.de/ - they have a freeware version which works
quite well for boards of moderate size and complexity. Schematic
entry, board layout, autorouter, Gerber and PostScript and HPGL
output, and it runs under either Windows or Linux.

> BR from Ivan

Hi Ivan,
This is a side issue, but the binaty vs. 'ternary' (? tertiary ?) is
not a problem as far as the computer is concerned. In the computer, the
dah, or dash is no different from three short lengths (baud) together which
happens in ASCII. Morse can be viewed as groups of the basic dot time, just
as is ASCII.
For CW decoding programs, this is an algorithm issue. How the
programmer chooses to decode the CW. As I was watching CWGet, I could see
that a dash which was shortened by fading, but still longer than a dot, was
decoded as a dot. A more intelligent algorithm would do better. The
computer can also be programmed to look for and adjust for irregularities in
the CW speed (and are auto speed already) and, to some extent, variations in
the "fist".
I believe the OP is trying to find a way to improve upon CW in low
signal to noise conditions. I believe is will be a long time before the
brain is rivaled. Anyone _know_ differently?

Message-ID: <ceu5ei$ltb@odah37.prod.google.com>
Source record: 24286

I am not, NOT mind you, an electronic whiz. In fact, I'm just starting to get into this hobby/phenom. But it occured to me...why not set up solar powered REPEATER STATIONS at 1/2 mile intervals around my base LPAM transmitter. Wouldn't that effectively enable me to cover about 5 square miles with a mini-am signal-network? Solar powered panels atop a small box that has both a receiver board and transmitter and re-transmits the signal coming from my base station. About the size of a pack of cigs I would figure. Heck, I could just tie-wrap them inconspicously around a tree branch here and there. Just a thought. There's got to be a way.
I'm a 'retired' radio dj. I was on the air for the better part of 20 years and I am excited at the possibility of doing a radio show from my home on, say AM1700. Why not?

1506. VIETNAM ROCK is ON-THE-AIR!

Source record: 24291

Steve,

Evidently I've confused a few people as well as yourself.

1) The frequency shift keying contains no intelligence, only clocking
along a time axis.

2) The phase shift keying contains no intelligence, only clocking
along the phase axis.

3) The audio tones being shifted contain no intelligence, only
clocking along the amplitude axis.

The pattern below describes the shifting between tones A and B

```
Phi-0 Phi1-1
| |
_ _ v_ _v Tone A ^
| | | | | | Frequency clocking.
|_| |_ _| |_| Tone B v
```

Note the phase directions at Phi-0 and Phi-1, each is the reverse
of the other.

Now, suppose the time unit is 10 millisecond. If I've done my job right
and can correctly detect the pattern to exist at each time
unit that the pattern travels through a special detector, and assuming
that our logic high from the detector runs a beeper, the human ear
should hear a solid beep for the 80 millisecond that the pattern
travels through the detector.

* * * * * * * *

Let's emit this pattern for just a couple time units longer:

```
_ _ _ _ _ _
| | | | | | Frequency clocking.
|_| |_ _| |_| Tone B v
```

so that we can hear a solid beep for 100 millisecond

* * * * * * * * * *

Now you can humor me and imagine a contracted time scale, where
a plus represents ten stars, this is also 100 millisecond.

+

and if we continue the pattern for 2000 millisecond, we can hear
a solid beep for that period of time.

+ + + + + + + + + + + + + + + + + + + +

So we now have the equivalent of an unbroken carrier. Suppose
we turn off our pattern emitter, our detector fails to lock
onto the carrier, and so we hear silence for those periods.

+ + + + + + + + + + + + + + +

And so we get the Morse letter K !!!

So, the pattern itself would be heard as morse code which
sounds like a buzzsaw on an ordinary receiver, at the
usual distance range.

If we place a special detector after the audio in an
ordinary receiver, the morse would be heard as a pure
tone from a greater distance without benefit of computer.

If we place a computer after the audio in an ordinary
receiver, then the morse would be heard at a greater
distance than can normally be detected by a computer.

Make more sense?

I actually asked for it and they gave it to me. The VE7AQS was a bit more complicated - they gave it to me by accident and I got stuck with it.

There was a bug in the HTML code when I posted the program up to my website.
And I forgot to check the program was down-loadable before advertising the
fact in newsgroups that it was available. Very remiss of me.

The bug was use of an upercase character in the program's name. I typed
"Radials2" instead of "radials2".

It took me 3 hours to find out precisely where the problem lay during which
time there were several hundred disappointed attempts to download the
program. I feel very guilty!

But for a private e-mail from a kind expert who diagnosed the problem I and
the customers, 24 hours later, would still have been thrashing about in the
dark.

Eternal, Top posting 'cuz U R.

No, I think I had it in the first place, or at least, was close. It's just difficult to express in few words. Lets see if I have it...

Although you don't say it, I thought that this "pattern" of phase shifts is not simply alternating phase shifts at regular intervals, but a definite pattern with some of the times between shifts being, lets say, twice as long, or 20ms. This pattern is what is unique and what your (so called "non computer") detector will be looking for to generate a "beep" (what you symbolize with the *) to be listened to, right?

I got this from your:

> ... I found no less than eight
> >>orthogonal logic conditions by which I could identify the
> >>presence of this pattern in at most 10 time units...

Assuming you have a basic understanding of PSK31, what I think you are proposing can be described in terms of PSK31. What if we simply use ONLY ONE letter of PSK-31. However, we send it over and over. This gives your detector something to recognize to ake the audio * beep for the listener. If is doesn't see that specific _pattern_, it won't make the * beep.

Then just key the whole thing on & off just like ordinary CW.

I don't have the code here, so I'll make something up and say we use a pattern of phase shifts like this:

_ _ _ __ Phase "A"

|||||||
||_||__||__||_ Phase "B"

Looking just at the Phase A part for simplicity, we have "short, short, pause, short, pause, long". If we did this correctly, we will not falsely decode this if we slip just one time slot in a longer string of these patterns. We must be in "bit sync". That is, the receiver system (not the ear-listening-to-the-audio-out-of-the-receiver), must "know" where we are in this pattern at all times.

This gives us 11 times or 110 ms. [[we need to set the timing so you can get one or more of the patterns into one Morse dot, but I'll ignore that for this discussion]]

Let's say this is a Morse DOT. String three of these together to get a dash - which will be 330 ms long. Sounds like pretty slow code, but in principle, this is what I thought you meant.

In reality, if this was a truly synchronous system, the pattern could actually be a truly pseudo-random pattern which doesn't repeat in such a short time, but may be seconds long. If we provide some "key-down" time at the start for the receiver to find its place in the pattern, and achieve "bit sync" this would also "work".

To firm up understanding, I compare this to the following "tone detector" system. Assume we have, for the moment, returned to ordinary CW. Tune your receiver for an 800 HZ tone and build an 800 Hz tone-detector. Use the output of this tone-detector to Key an audio oscillator to produce a "* beep" which you can listen to and copy the CW with.

What I have for your Phase shift system, simply replaces the CW with this PSK pattern and the tone-detector with a "phase shift pattern detector".

This is certainly "a way", but the problem of the modulation sidebands is still there. The ear will hear a T6 Morse signal, but your demodulator system still needs considerable computing (or calculating) power if using "circuitry" of some kind.

In my previous post, I mentioned the calculations for FM not PM, but the result has to be similar. The filtering used to define your phase shift transition times will determine the modulation index and therefore the bandwidth. 100 Hz modulation is 100Hz modulation and the sidebands need to be there at the demodulator to demodulate the waveform and the receiver will still require a 200Hz bandwidth. It will also have to be something rivaling a computer to sync up and detect the pattern so it can properly "know" when it is present and when it is absent and make the beep for the "enhanced system" CW operator.

So it seems to me that you have a 200HZ CW system and that can't be better than the standard 10HZ or whatever it is---not to mention the ability of the ear-brain to pull CW out of the noise. The *ORIGINAL* DSP, no?.

Make sense?

Maybe they'll open an RF FETs 'R' Us soon?

Seriously, it seems to be getting worse, at least around here. The Active Electronics store that opened a few years ago is now closed, and one of the big distributors in the area abruptly disappeared (not the building, but apparently all of its contents and employees). That leaves a new Fry's, which doesn't seem to be much for semiconductors, and one old dependable TV parts distributor 50 miles from here... and, of course, a few places with $50 minimum orders who don't seem to like cash or checks.

This is called a product detector. It has been around for several decades now and involves a mixer and an oscillator at close to the same frequency as the receiver IF (say, 800 Hz off), the oscillator being called a Beat Frequency Oscillator (BFO). Usually it is placed before the audio stages, however. By the way, with the mixer/BFO scheme you can do away with the buzz saw signal and it will still work just fine.

But not at as great a distance as a human ear! Besides, distance has nothing to do with it. Instead it is the ratio of signal to noise at the receiver output.

Don't forget Alphatronics in Southcenter (or Supertronics, or whatever
they're calling themselves these days). Whenever I go to Fry's, I
usually end up need to go by there for something Fry's didn't have, and
vice versa.

Fry's actually does pretty well in the semiconductor department if you
don't mind using NTE crossrefs for everything. They are better at
stocking semiconductors than, say, resistors.

Hi JLB,
Me thinkth that Eternal was trying to describe something that detects his special phase modulated 'code' rather than just mix the carrier down to audio. I'm not sure, but I think the idea was that it should be possible to detect the "narrow", phase modulated signal at lower S/N due to the reduced bandwidth. I have been trying to determine the basis for his thoughts in my posts... Waiting for his response.

I'm of that opinion, as well. The ear-brain is a wonderful CW signal processor. Quite amazing.

> There's got to be a way.
> I'm a 'retired' radio dj.

OK. the answer is yes, this is "possible".

Here's my take...

HOWEVER, to do it, requires you to *become* a whiz, so to speak...

IF you want to stay legal, what frequency will you use TO your repeaters @
said 1/2 mile distance? That's quite a distance for part 15 stuff.

Then:
I wouldn't expect to get 1/2 mile (for pickup on an ordinary AM radio) on
the AM band with something the size of a deck of cards. If you were a DJ,
I'm sure you remember those large antennas used on AM. There's a reason. I
believe the biggest problem for the LPAM transmission is getting energy into
the air. The guy across the 3/4 mile wide lake from me is trying to do it
legally and in no way can I pick up even a hint of his carrier with my 40M
dipole, much less listen in on am AN radio.
If you string lots of wire between the trees, perhaps you can get somewhere
with lots of these & lots of wire. However, I believe there's the antenna
size limits, as I recall.

Then there's the batteries & solar cells. All I can say is Yep, just shell
out the $$, but you'll be outside your size by far. Then mounting solar
cells around the neighborhood is tricky - not _IN_ the trees, for sure. I
don't know the power limits off hand, but you'll need batteries (who's
listening daytime?) for night time.

In the 60's one of the fellas got several miles (just barely) with 50 watts
and a long wire - strictly outside the law.

If the FCC doesn't scare you, then all bets are off.

Finally, I'd ask, who listens to AM anymore? All I hear is Sports
stations, Spanish and News radio 78 in the Chi town far burbs. Of course
there's the odd crystal set folks. Are you thinking that nam vets will
listen? Maybe I should tune in to your web-cast to see what you offer, but
I don't listen anymore...

OK that wasn't final... The suggestion for the Web resources is good,
HOWEVER, there are both "Legal" type groups and then there's the pirates.
As we used to say in Boy Scout camp:
Clean mind, clean body.

Take your pick.

'gards, Steve N, K,9;d,c.i My email has no u's.
PS. I got...er...um...I mean, that is, I hear that someone, somewhere got around a mile and a half, maybe two with a 1/2 watt on FM., 104.7, and a 5/8 vertical @ 35 ft. Great fun, two carts, call-ins, swiped commercials, but it was always a phone tree when we were on...er... um, I mean, that is, when whomever they were, were supposedly on.

Well, he said that he wanted it to be useable by people in third world countries that do not have computers. Most likely they would have a typical receiver with a bandwidth of 250 to 500 Hz, maybe up to 3 kHz, with a BFO and product detector. In this case, the narrow shift/phase deviation would be lost in the noise anyway.

Methinks one should study wheel theory first, before trying to invent a new one, don't you agree?

Jim

No problem, Reg. I checked again the next day and you had obviously fixed
the link so I downloaded the program and spent some time playing with it,
using one of my own antennas as an example. Very nice program and there
are "some antenna improvements" for me to make here HI.

Thanks again for your good work. You are an asset to us all. More power
to you!

Keeping within the 10 foot antenna limitations, you can easily achieve
distances
of over I mile coverage on frequencies above 1600 kHz. Check the Radio Free
Allston (Boston, MA microbroadcaster on 1630 kHz) webpages.
They are covering a large area of the Allston Brighton area of Boston,
and have gained some recognition for their public service orientated
programming.
I've copied them at distances over 2 miles when leaving Boston on the Mass
Turnpike.

The SSTran website (www.sstran.com) shows how to build a fairly decent
antenna for their part 15 AM transmitter.

Steve,

Yeah, I think we agree, I am attempting to send and receive manual CW over something resembling a PSK transport layer, that reads as T6 manual CW to the unassisted ear.

I had read about the advantages of PSK-31 and I wanted to see if I could somehow adopt some of those advantages to manual CW with the assistance of simplified dedicated circuitry.

I know that CCW was the precursor to PSK-31 but that it fell out of favor due to the need to make it "perfect CW", to synchronize the dot as the smallest time unit, so that it was effectively a real PITA to use by operators.

Still, the ability of CCW or PSK-31 to effectively borrow received signal strength from a broadcasted time standard, by synchronizing the dot against the standard, is a tactic worth stealing.

It seems to me that if I could build a dot out of a series of smaller time units that were synchronized with a standard, then I would have the flexibility of manual keying and also inherit the advantages of CCW or PSK-31.

What I someone to explain to me, is the math foundation behind the enhanced received signal strength of CCW or PSK-31 over conventional OOK of a simple carrier. I do understand, in rough terms, about how my modulation index might be excessive, but maybe if my modulation index is the same as PSK-31's I can keep the enhanced received signal strength advantage?

I still remember integral calculus, my understanding of differential equations was never too good but parts are till in my head, but unfortunately we never covered modulation indexes or power spectrums in my graduate signals and systems course. It was all transfer functions and laplacian transforms at that time.

I'm a bit better at discrete math, symbolic logic, digital design, and I write engineering tools software for a living. From my hobby at home I am just beginning to make up for all my C's and D's in analog circuit design, and LTSpice is a great help there.

If you can explain whether my approach might work or won't work to me in mild engineering math I might have a half a chance feeling comfortable in either going forward or abandoning it.

There's nothing holy about the 10 ms time unit, I just used that for purposes of illustration.

Now, as far as the dedicated receive circuitry, I have in mind the following:

1) Filtered tones A and B come into respective frequency comparator circuitry that compares the incoming tones against reference tones A-prime and B-prime. The frequency comparator emits a logic high when the comparator matches a tone against its tone-prime.

2) The output of each frequency comparator is sent through respective digital smoothing circuitry to make up for intermittent dropouts due to fading on each tone.

The logic level output of the frequency comparator is fed into a 10-bit shift register clocked 10 times faster than our original time unit, or 1 ms. The output bits of the shift register are fed into an 10-bit input to 1-bit output EPROM.

The smoother EPROM pattern is such that a logic high will result when at least 8 out of any 10 bits coming from the shift register are high.

3) The output of each smoother is fed through respective digital sampling circuitry.

The sampler circuit is simply another 10-bit shift register, this time clocked at the original time unit.

4) There are now 10 bits coming from sampler A, and 10 bits coming from sampler B. The outputs of the samplers are combined by feeding all 20 bits into a 20-bit input to 1 bit output EPROM.

The decoder EPROM pattern is such that a logic high will result when a fraction, say half, of those 8 orthogonal measures I spoke of in an earlier email hold true for the duration of the original time unit of 10 ms.

I can easily work out all the possible patterns of 20-bits that would hold true using an exhaustive search on a computer.

(So yes, I do have to use computer power like you said, but fortunately, I only have use it once for decoding a single PSK-type character that will never change.)

5) The output of the decoder EPROM is sent into the beeper or buzzer of your choice.

Does this make sense?

The Eternal Squire

(P.S.. yes, I have a name and a ham call, but I prefer my privacy. I'll be happy to give them to you over private correspondence. However, since I want to get as many signal theory elmers into this as I can

to hopefully either invalidate or bullet-proof the theory before I
start building and testing, I hope you don't mind taking part in a
public discussion).

Well, my Vibroplex, a J-36 WWII surplus model uses mostly SAE 8-32 and 6-32 (some call those "NF" threads) for the hardware. The pendulum spring material of choice was once an inch or two length of clock spring..... the mainspring from a "Big Ben" alarm clock was about right. Trouble was attaching the ends of the spring to anything without destroying the spring itself. The factory model had holes in the spring and rivets were used to attach both ends of the spring. Two rivets on each end. Another source of spring material, once common, not so common anymore (to me, at least) is corset springs. The most radical of the corsets had pretty skookum springs.

Two approaches spring to mind...

1. Using the ubiquitous "Dremel" styled miniature
grinding wheels, grind fixing holes in the spring.

2. Using gas flame and water bath, first soften for
drilling, then harden and temper to Blue/purple colour.

Steve,

Okay, I don't need the math after all. I surfed and finally found some theory foundation regarding PSK-31:

http://www.arrl.org/tis/info/pdf/x9907003.pdf
http://www.arrl.org/tis/info/pdf/59941.pdf

Reading these, I can finally agree with you that BPSK is a better transport layer than the phase-coded, synchronized FSK I was considering. Since it is self-clocking, I would not even need a seperate clock station like WWV or WWVB.

Reading what you have been telling me about character selection, it seems that sound the tone whenever I detect the shortest Variode sequence possible, the space character, followed by a single idle code.

The space character is a simple 1, and a single idle code would be a pair of zeroes.

That way the absence of my sequence should squelch the PSK software on your end, or its equivalent in my dedicated decoder hardware. Squelch would form the space between tones.

I can still use a pair of shift registers and an EPROM to detect the difference between the minimal pattern and squelch.

Better?

The Eternal Squire

>them how to calculate how much wire to wrap for a partical inductance value.
>Etc...

For a comprehensive design program on toroidal core inductors,
go to:

http://www.micrometals.com/software_index.html

and choose a "low frequency" version for power inductors
(Micro_vMar20.exe ~812K) or a "DC to 300 MHz" version for
RF inductors (Toroid.zip ~400K). Free downloads.

Micrometals has been in the iron powder core business for three
decades plus and the information on their website as well as their
famous "Q Book" is accurate, reproducible.

The "Amidon" toroid cores sold to radio amateurs for years in
small quantities through various stores comes from Micrometals.
Their nomenclature comes from Micrometals.

A toroidal core keeps the magnetic field IN the torus (doughnut
shape) and is much less influenced by nearby conductors or even
dielectric material. They are slightly harder to wind than the
solenoidal type (have to do threading through the center hole) but
that becomes easy with slight practice. I've used Micrometals
cores for over three decades with success, both in small prototype
quantities and in large production lots.

The Toroid.zip package is good for determining number of turns and
layers for RF inductors as well as showing the effect of various iron
powder types ("mixes"). If you don't know the mix of the powder in
your cores, you can get a good handle on them by winding
according to the computer programs and measuring the inductance

(by whatever other means you have...I would recommend the AADE
L/C Meter for those who don't have access to a Q Meter).

Pardon the delay to an old thread. Catching up after HD change.
I just checked the Micrometals website and they are current.

:IT

Found it in my old data books. Pretty simple.

MX20-2 440-470 MHz 20W
3 stages of amplification. 50 ohm, Min Gain 21 dB

Pin 1 RF In (max 150mW)
pin 2 gnd
pin 3 Vcc1

pin 4 Vcc2
pin 5 gnd
pin 6 RF Out

Vcc 1&2 typically 12.5V, Max 15.6

Vcc1 feeds first 2 stages
Vcc2 final

Test setup shows inductor in series with Vcc and bypass caps at the
device. I can't see anything in datasheet about which end is pin 1, but
it is symetrical, so if you get it backwards, you should just have no
gain.

1540. Sinadder schematic

Newsgroup: rec.radio.amateur.homebrew

I am interested in making a Sinadder meter.
If anyone has a schematic could I ask for a scan please.

Thanks

Excellent work, Rex. Thanks very much indeed. I'm a bit pissed off
about the Pout, though. It was advertised as 30W, not 20 as it
actually appears now to be. :-(
It came wrapped in anti-static stuff but surely there's no need to
worry about static with this type of device? I can't imagine it would
have anything other than BJTs in it. :-|

You can use a Vector Voltmeter like the HP8405A (up to 1300 MHz),
and a signal generator. The test will be done on a single
frequency but the 8405 support some low manually sweep of the
frequency to cover the bandwith you test.
A 8405 can be found at cheap prices and is cheapest than a VNA.

20 W instead of 30 W means 1.8 dB less .....a fraction of an S-point
Would be surprising if any rx would sense the difference.
Enjoy the use of that module ,Paul .

Steve,

Okay, I don't need the math after all. I surfed and finally found some theory foundation regarding PSK-31:

http://www.arrl.org/tis/info/pdf/x9907003.pdf
http://www.arrl.org/tis/info/pdf/59941.pdf

Reading these, I can finally agree with you that BPSK is a better transport layer than the phase-coded, synchronized FSK I was considering. Since it is self-clocking, I would not even need a seperate clock station like WWV or WWVB.

Reading what you have been telling me about character selection, it seems that sound the tone whenever I detect the shortest Variode sequence possible, the space character, followed by a single idle code.

The space character is a simple 1, and a single idle code would be a pair of zeroes.

That way the absence of my sequence should squelch the PSK software on your end, or its equivalent in my dedicated decoder hardware. Squelch would form the space between tones.

I can still use a pair of shift registers and an EPROM to detect the difference between the minimal pattern and squelch.

Better?

The Eternal Squire

I have never tried but you may want to hook them up using a Wilkerson type circuit. Feed them by using a 1/4 wave line on the input and output and a 100 ohm resistor . At 2 meters and up this should be easy to do.

1554. Ft for RF transistor

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-08 21:51:02 UTC
From: SBC <braymond@ameritech.net>
Message-ID: <afxRc.908$ZC7.325@newssvr19.news.prodigy.com>
Source record: 24236

Well, I picked up a couple of Mitsubishi 2SC2166s to play with. I'm interested in using the transistor for HF or low VHF. I'm only playing, so nothing I do is critical. I just want to see what I can make the transistors do.

I'd like to design a circuit, model it, and then mock it up and see how close I come with my model. The gotcha is that the datasheet shows just about everything I think I need except for the gain-bandwidth product (Ft). I'm doing my modeling based upon Wes Hayward's Introduction to RF Design (absolutely wonderful book) and EMRFD (not bad, either).

My first question - is this just a fool's errand? In other words, is this transistor just typecast for CB finals and for some reason it's not possible to use it for anything else?

My second question - assuming the answer to question #1 is no, is there a reasonable way to estimate Ft from the other data (such as Zin and Zout)? I'm generally suspicious of any derived values, but in this case derived data would be better than nothing. I'm assuming the Ft is probably somewhere between 100-200 MHz, but that's just a guess.

Thanks for you help,
Bruce Raymond/ND8I

1555. Re: Ft for RF transistor

Newsgroup: rec.radio.amateur.homebrew

From: TOM <noname@noprovider.nodomain>
Message-ID: <CVARc.6441$114.3053@nwrddc02.gnilink.net>
Source record: 24237

All the datasheets seem to be missing the Ft for this part. Other parts in
the same family have Ft in the
100 MHz range for the 6 amp die, and 150 MHz for the 3 amp die, so a good
guess for the 4 amp
one (2sc2166) should be about 150 MHz.

Searched my datasheets, HF-Low, (27Mhz), working frequentie.
Working frequentie is most the time 1/10 of the Ft, Ft is 270Mhz ?
Ft increases with higher Ic, draw more current en cool the transistor,
should make it working at higher frequenties !
Greetings Bas.
Whished a had the book you mentioned !
Not available in Europe, available by ARRL America, delivering time
half a year.

Just got back from a cruise to Alaska. Took my Sony 7600GR with my. Sitting on the top deck at night I could get 6-10 beacons, US and Canada, using just the internal antenna. I guess bush pilots still use the beacons.

HF was also really good. At the WWV and WWVH signals came in easily.

Steve.

It would appear that even if one purchases PL259's intended for large coax, that there remain differences, eg, if there is a shoulder just below the screwed portion where the reducer might go in, then it is intended for the slightly smaller large diameter coaxes. Is this the case?

(Never had this problem when we all used Belling-Lee connectors and UHF TV coax!)

Yes, with the proper reducer one could use RG-58U and or RG-8X (or as it is sometimes called RG-8u modified) the 8X is much better than the 58U. A tad thicker
than 58u but much heavier center conductor and a better shield. This can handle much more power also. I use it all the time. The reducer needed is UG-176/U (8X is the thickness of RG-59U that is used on cable systems)
cheers!

Message-ID: <2np4taF2jbmgU1@uni-berlin.de>
Source record: 24244
Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew

I was recently commissioning a 2M vertical antenna that
had an in-built SO239. However, the thread on the SO239
was shorter than that of a PL259 to the extent that even when
screwed fully home, the cable was not locked (Usually by
those triangular pips on the end of the plug locating into
the v-grooves on the SO239) and could
swivel around with a correspondingly poor contact
for the braid/outer.

The solution was inspired by the new bathroom which
we installed recently, in particular, the use of (Yorkshire?)
compression fittings with their olives to join lengths
of copper pipe.

The method is to completely unscrew the PL259's nut off
the plug, and to wrap some braid off a piece of scrap coax
around the cable end of the plug. When the nut is now
tightened down, the braid is compressed and acts to lock
down the PL259 by reducing the length of screw thread that
is available to mate with the SO239

Hmm. Doesn't sound like the sort of question I'd expect from a regular home
brewer.

Just how much construction have you done?

This is the sort of bodge job you used in your software. Wasn't it.

Ask Westinghouse.

Even a Cber would know that your problem is caused by
trying to mate up 2 incompatible threads!!!

It is a common problem on white stick antennas, if you
purchase a compatible plug then everything will screw up
correctly.!!!!!

Jeff

I read somewhere that the cheaper Svetlana 4CX800A can be used as a substitute for the Eimac 3CX800A7. Does anyone know if the Svetlana tube also uses beam forming? Would I notice a difference at audio frequencies? (I'm serious)
Also, can this tube be used in class A? On Eimac's site, it says it's designed for class B, but does that mean that it merely won't be as efficient in class A, or it will blow up, or what?

The '3' in 3CX800 means triode, the '4' in 4CX800 means tetrode -- so they won't be compatible.

I have no idea of the potential for high-fidelity audio of either tube, but either one should make fine audio amplifiers otherwise.

Per basic amplifier theory no tube will be as efficient in class A -- the theoretical maximum you can get in class A with a pure sine wave input and a plate choke or transformer is 50%, in class B this goes up to something like 63%.

Any normal* tube can be used in any class of amplifier as long as you don't exceed the various design limits of the tube. In designating it for class B Eimac means that the design limits are sized for such, and in class A operation you'll have to hold a number of them way below maximum to keep the few (plate dissipation, mostly) in line.

Either one of these tubes should be electrically quite suitable for class A operation -- but you have to design the circuit right, and understand the implications of everything that you do. I don't want to discourage you, but the nature of your question tells me that you need to do some serious study (possibly including blowing up some lesser tubes) before you tackle this one.

* and if you find one that can't I'll say it ain't normal!

Hi Eternal,

All this IS indeed possible. However, I believe the issue is the low signal to noise performance. I think your reasoning it all based on clean signals and I would ask about the situation where the digital data has a glitch due to just enough noise to start causing errors. The pattern you are looking for has been corrupted and the A/D-converter-shift-register-EPROM bits are not what you are looking for. All the push to digital communications is not based on a need for better low S/N capability, but rather better data capability, and in my opinion, a side effect of this is actually poorer low S/N capability. However, we make the system operate such that have the power to make up for it.

I'll close by saying that I feel that this won't be better than copying by ear, but worse. From what I have seen, digital systems work great down the error threshold, then they completely fall apart, not gradually, but completely---fall off a cliff. The ear/brain system has phenomenal low-signal-to-noise-ratio processing ability.
Go ahead and prototype something and prove me wrong, then I'll say, "Gee, I think you've got something there" and I'll be humbled jus a bit more...

No,

you will find that there are 2 different threads available,
quite a few 'white stick' antennas use a metric thread.
A non-metric thread plug will screw on most of the way
and then jam, leaving the centre of the plug free to
rotate. Solution buy a plug with the correct thread.

Jeff

A metric PL259? Well, there's a thing!

Do the sellers of Ham Antennae stress that their
SO239 connectors need a special plug?

It may be that what you say is true, but I am sceptical.

I'd consider one of the common antenna impedance analyzers, but I don' know
what the output level is. Scope & sig gen is asking a lot unless you think
you can measure RF voltage and current magnitudes and phase while driving
the device with its "normal" signal level.
If you are talking about RF power transistors, the pros use matching devices
like shorted stubs and stretch lines to get power out, then remove the
device and measure the matching networks with the available equipment. Good
luck.

The spacing of the frequencies depends on the capacitor and the rest of the
circuitry.

I was going to buy a Palomar VLF converter for my FT-857D
but stumbled on this website:

http://home.att.net/~jacksonharbor/lfconv.htm

For $12 shipped I got a kit which took an hour to assemble, taking
my time & trying to do a good cosmetic job on the breathmints tin
that holds the project.

$99+shipping for the Palomar? Forget that! This thing rocks! I
ordered the 14 mhz version and on a 134' dipole I'm hearing
WWVB (60kc) LOUD! I'm also picking up a 100w 100' antenna
NDB on 261 kc about S9+20. The co-ordinates for this beacon
are about 21 miles away, due south.

The DGPS signal at 306kc is even louder - S9+50!

It's easy to build with only 1 trimmer cap to set the conversion
rate. I used the program CWGET to measure WWVB at a dial
indicated 1000hz offset. CWGET allowed me to adjust the VLF
converter to +/- 1hz! Neato!

Not too shabby for $12 shipped!

Pics on request....

news:Xns955E522A794FAGormenghast@64.59.144.76:

I should have mentioned what I'm driving: plasma. Class A is not at all inefficient in my application, as the bias power is not wasted but goes into maintaining the plasma. So it's essentially an AF modulated plasma driver. I know Hill's Plasmatronic speakers from the late 70s use that mode of operation, but I'm doing it with air plasma instead of having to use a helium tank. The V-I characteristic of the glow discharge is such that voltage varies very little with current in the range that matters, so essentially I need a 2-3 kV tansconductance amplifier. As few of Hill's creations exist, I haven't found anyone with a circuit diagram yet, and the patent doesn't give details of the amplifier, concentrating instead on the plasma parameters. I know he used 6MJ6 tubes, but that won't work in my case since I'm using air and need higher voltage. It's single ended since the down swing of the sound wave depends on the plasma thermal relaxation constant and is not really independent of the amplifier.

Here's an idea that's just whacky enough that it might work...has anyone tried it?

If you have a dual-trace scope with enough bandwidth, you might be able use Lissajous patterns. The idea would be to drive the complex load through a directional coupler with fairly good directivity. A sample of the incident signal would go into the scope X input and a sample of the reflected signal would go into the Y input. With a pure reactance as a calibration load, adjust the X and Y scope gain for a perfect circle on the display. Replace the test load with a complex load, and the magnitude and inclination of the line/oval display can tell you amplitude and phase of the reflected signal, from which any other metric can be calculated.

These are indeed a fabulous buy. A number of the LF gang have purchased
them. The only drawback I have heard is that they are apparently not stable
enough for the slower QRSS modes via Argo- although I have no personal
experience.
For NDB's though- these would be a great choice.

Why. You have to run the thing to catch it. I have the defaults
turned off, I use Agent as a news reader, and Firefox as a Browser..

You should see the code in some of these. They are adding Netscape as
well as Explorer.

How about "meter.exe" which is in the files downloadable by
those who have purchased the ARRL 2004 handbook - caution -
you might need to actually buy the handbook in order to
obtain a valid licence to use the software, but then, if you have
done so, you'll know the URL, so problem solved!

Another contributor, "Jeff", has intimated that PL259's
are available in metric form.

Is this true?

If so, how does one find out which version of the SO239
is fitted to equipment?

Is the modern (say, more recent than 10 years old) Jap
gear fitted with these later plugs?

When one buys plugs and sockets from the rallies, which
ones is one getting?

Presumably there's no such thing as metric plugs in Yankland?

Thanks for that, Walt - perhaps now is the time to scream
about "grey" imports if these were intended only for the internal
Japanese Market?

Unfortunately the Diamond colinear to replace the 5/8ths suffered
from the same problem, and the cable is jammed solidly onto the
antenna, so we may be stuck with it! I assumed that the lower part of the
SO239's screw thread was dirty and so drove the nut home with a
pair of pliers, assuming that this would clear the screw thread - we live
and learn!

I'm now well on the way to repairing the 5/8ths where I had to
engage in destructive test - I've been given a large sheet of
Paxolin/Tufnol which is 7/8ths of an inch thick, so 3 thicknesses
of that araldited together and turned down should do the
trick.

There are. Metric M4 PL259/SO39.

Don't know how you tell the difference other than
by trial and error. PLs don't usually have any
distinguishing markings.

Thats because its different trojaned machines that send them. Caused
by brain deads that constantly Open these things.

Ho, Ho, Ho

Yet another fettling experiment that went wrong!
I'm so glad that I'm only a beginer, and not an expert like yourself...

The term "PL259" grew out of a military spec. You may have a metric
connector that _resembles_ a PL259 but it ain't a PL259.

Ahhh. Got it. Not sure just what you need to start from. Starting from scratch isn't very hard. I have an Excel sheet that does circular dials in a chart You use formulas to determine the spacing, so non linear is possible. I got the method from a post on one of the amateur radio groups. Email if you think this will help. If it is a linear (slide rule dial), then any drawing program (including Excel) will do that as well.
